This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

IRON AND STEEL	3–83
The iron and steel industry	3–22
Table 1.—Iron and steel—comparative summary, with per cent of increase: 1870 to 1905	4
Table 2.—Iron and steel—comparative summary, by states: 1880 to 1905	5
Comparative production by states	7
Table 3.—Iron and steel—quantity of classified products, by states, with rank of states: 1870 to 1905	7
Capital	8
Table 4.—Iron and steel—active and idle establishments—capital: 1880 to 1905	8
Table 5.—Iron and steel—active and idle establishments—capital, by branches: 1880 to 1905	8
Table 6.—Iron and steel—active and idle establishments—capital, by states: 1880 to 1905	9
Miscellaneous expenses	10
Wage-earners	10
Table 7.—Iron and steel—wage-earners (men, women, and children), with per cent of total, by branches: 1880 to 1905.	11
Materials used	11
Table 8.—Iron and steel—fuel consumed, by kind, quantity, and cost, by branches: 1880 to 1905	12
Table 9.—Iron and steel—quantity and cost of iron ore, mill cinder, and fluxing material consumed, by branches: 1880 to 1905	13
Table 10.—Iron and steel—quantity and cost of iron and steel used as material: 1880 to 1905	13
Production of iron and steel	13
Table 11.—Iron and steel—quantity of classified products, with per cent of increase, by branches: 1880 to 1905	14
Number, equipment, and capacity of iron and steel establishments	14
Table 12.—Iron and steel—active and idle establishments—number, equipment, and capacity: 1880 to 1905	14
Table 13.—Iron and steel—establishments, other than steel works and rolling mills, having steel works or rolling mill equipment: 1905	15
Iron and steel industry, by geographic divisions	15
Table 14.—Iron and steel—comparative summary, by branches and geographic divisions: 1880 to 1905	16
Table 15.—Iron and steel—per cent of increase in principal items, by branches and geographic divisions: 1880 to 1905.	18
Table 16.—Iron and steel—per cent of total capital and products, by branches and geographic divisions: 1880 to 1905.	20
Per cent of total value and quantity of products, by branches and geographic divisions: 1880 to 1905	21
The New England states	21
The Middle states	21
The Southern states	22
The Western states	22
The electrothermic metallurgy of iron and steel	22–24
Blast furnaces	24–48
Table 17.—Blast furnaces—comparative summary, with per cent of increase: 1870 to 1905	25
Relation of capital and specified items of expense to products	25
Table 18.—Blast furnaces—comparative summary, by states: 1880 to 1905	27
Capital	28
Table 19.—Blast furnaces—active and idle establishments—capital: 1880 to 1905	28
Materials used	28
Table 20.—Blast furnaces—materials used, by kind, quantity, and cost, with per cent of increase: 1880 to 1905	28
Products	29
Table 21.—Blast furnaces—production of pig iron, including direct castings, classified according to kind of fuel used, with per cent of total: 1880 to 1905	29
Table 22.—Blast furnaces—quantity and value of products classified according to kind of fuel used, with per cent of increase: 1880 to 1905	29
Table 23.—Blast furnaces—quantity and value of all kinds of pig iron, with average value per ton, by states: 1880 to 1905	30
Table 24.—Blast furnaces—quantity of pig iron, by grades, with number of establishments reporting, by states: 1905 and 1900	32

IRON AND STEEL—Continued. Page.
Blast furnaces—Continued.
Products—Continued.
Table 25.—Blast furnaces—quantity and value of direct castings, and spiegeleisen and ferromanganese, classified according to the kind of fuel used: 1905 and 1900 ... 35
Pig iron production, distributed by classes of establishments and by states: 1905 ... 35
Quantity of metal, classified according to method of handling, by states: 1905 ... 36
Equipment and production ... 36
Table 26.—Blast furnaces—number of active and idle furnaces and production of pig iron, with per cent of total, by states, ranked according to quantity of product: 1880 to 1905 ... 36
Table 27.—Blast furnaces—number of active and idle furnaces, by states: 1905 and 1900 ... 37
Table 28.—Blast furnaces—number and capacity of completed furnaces, classified according to kind of fuel used, by states: 1880 to 1905 ... 38
Slag pits ... 40
Pig iron exported ... 40
Power ... 40
The manufacture of pig iron with mineral fuel ... 41
Table 29.—Blast furnaces, mineral fuel—comparative summary, with per cent of increase: 1880 to 1905 ... 41
Table 30.—Blast furnaces, mineral fuel—comparative summary, by states: 1880 to 1905 ... 42
Capital ... 43
Table 31.—Blast furnaces, mineral fuel—active and idle establishments—capital: 1880 to 1905 ... 43
Materials used ... 43
Table 32.—Blast furnaces, mineral fuel—materials used, by kind, quantity, and cost: 1880 to 1905 ... 43
Materials consumed per ton of pig iron—mineral fuel ... 44
Products ... 44
Table 33.—Blast furnaces, mineral fuel—products, by quantity and value, classified according to kind of fuel used: 1880 to 1905 ... 44
Table 34.—Blast furnaces, mineral fuel—quantity and value of pig iron, with average value per ton, by states: 1880 to 1905 ... 45
Dry-air blast ... 45
The manufacture of charcoal pig iron ... 46
Table 35.—Blast furnaces, charcoal—comparative summary, with per cent of increase: 1880 to 1905 ... 46
Capital ... 47
Table 36.—Blast furnaces, charcoal—active and idle establishments—capital: 1880 to 1905 ... 47
Materials used ... 47
Table 37.—Blast furnaces, charcoal—materials used, by kind, quantity, and cost: 1880 to 1905 ... 47
Products ... 48
Table 38.—Blast furnaces, charcoal—products, by kind, quantity, and value: 1880 to 1905 ... 48
Table 39.—Blast furnaces, charcoal—quantity and value of pig iron, with average value per ton: 1880 to 1905 ... 48
Steel works and rolling mills ... 48–70
Table 40.—Steel works and rolling mills—comparative summary, with per cent of increase: 1870 to 1905 ... 49
Table 41.—Steel works and rolling mills—comparative summary, by states: 1880 to 1905 ... 49
Capital ... 51
Table 42.—Steel works and rolling mills—active and idle establishments—capital: 1880 to 1905 ... 51
Materials used ... 51
Table 43.—Steel works and rolling mills—materials used, by kind, quantity, and cost, with per cent of increase: 1880 to 1905 ... 52
Products ... 52
Table 44.—Steel works and rolling mills—products, by kind, quantity, and value: 1880 to 1905 ... 52
Table 45.—Steel works and rolling mills—detailed summary of products: 1905 ... 53
Iron and steel rails ... 53
Splice bars ... 54
Bars and rods ... 54
Wire rods ... 54
Structural shapes ... 54
Iron and steel hoops, bands, cotton ties, and skelp ... 54
Car axles ... 55
Muck and scrap bar produced for sale ... 55
Boiler and other plates and sheets, except nail and tack plates, black plates or sheets for tinning, and armor plate ... 55
Nail and tack plate ... 55
Black plates or sheets for tinning ... 55
Armor plate and gun forgings ... 56
Rolled blooms, slabs, billets, tin-plate bars, and sheet bars produced for sale ... 56
Steel ingots produced for sale ... 56
Direct steel castings ... 56
Miscellaneous rolled products ... 56
Miscellaneous forged, cast, or other iron and steel products ... 56

IRON AND STEEL—Continued. Page.
Steel works and rolling mills—Continued.
Products—Continued.
Total production of steel castings and of rolled and forged iron and steel, by states ... 56
Table 46.—Steel works and rolling mills—quantity of classified products, with per cent of total, by states: 1880 to 1905 ... 57
Miscellaneous secondary products ... 57
Nails ... 57
Table 47.—Steel works and rolling mills—principal iron and steel miscellaneous secondary products of rolling mills and establishments other than rolling mills: 1905 ... 58
Wire ... 59
Wire manufactured—comparative summary: 1905 and 1900 ... 59
Bolts, nuts, rivets, forged spikes, washers, etc ... 59
Wrought pipe ... 60
Seamless-drawn, clinched, brazed, etc., pipe or tubes ... 60
Horse and mule shoes ... 60
Springs ... 60
Equipment ... 60
Table 48.—Steel works and rolling mills—active and idle establishments—number, equipment, and capacity: 1880 to 1905 ... 61
Steel production ... 61
Table 49.—Steel works—quantity of steel ingots and direct steel castings, by states: 1880 to 1905 ... 61
Table 50.—Steel works—capacity of plants and quantity and value of steel ingots and castings, by states: 1905 ... 63
Table 51.—Steel works—quantity and value of steel ingots, by kind and states: 1905 ... 63
Table 52.—Steel works—quantity and value of steel castings, by kind and states: 1905 ... 64
Bessemer steel ... 64
Table 53.—Bessemer steel works—number, equipment, and capacity of establishments, and quantity and value of ingots and castings, by states: 1905 ... 64
Table 54.—Bessemer steel works—number, kind, and capacity of converters, by states: 1905 ... 65
Open-hearth steel ... 65
Table 55.—Open-hearth steel works—number of establishments and furnaces, and quantity and value of steel produced, by states: 1905 ... 66
Table 56.—Open-hearth steel works—quantity and value of ingots and castings, by kind and states: 1905 ... 67
Table 57.—Open-hearth steel works—number and daily capacity of acid and basic furnaces, by states: 1905 and 1900 ... 68
Crucible and miscellaneous steels ... 69
Table 58.—Crucible steel works—number, equipment, and capacity of establishments, and quantity and value of ingots and castings, by states: 1905 ... 69
Forges and bloomeries ... 70, 71
Table 59.—Forges and bloomeries—comparative summary: 1870 to 1905 ... 70
Table 60.—Forges and bloomeries—active and idle establishments—capital: 1880 to 1905 ... 70
Table 61.—Forges and bloomeries—materials used, by kind, quantity, and cost: 1880 to 1905 ... 71
Table 62.—Forges and bloomeries—products, by kind, quantity, and value: 1880 to 1905 ... 71
Table 63.—Blast furnaces—detailed summary, by states: 1905 ... 72
Table 64.—Blast furnaces—idle establishments—capital, equipment and capacity, and power, by states: 1905 ... 76
Table 65.—Steel works and rolling mills—detailed summary, by states: 1905 ... 76
Table 66.—Steel works and rolling mills—idle establishments—capital, equipment and capacity, and power, by states: 1905 ... 82
TIN AND TERNE PLATE ... 87–97
The combined industry—tin and terne dipping and black plate ... 87–90
Table 1.—Combined industry—comparative summary, with per cent of increase: 1905 and 1900 ... 87
Table 2.—Combined industry—active and idle establishments—capital, by industries: 1905 and 1900 ... 88
Table 3.—Combined industry—active and idle establishments—capital: 1905 and 1900 ... 88
Table 4.—Combined industry—comparative summary, by states: 1905 and 1900 ... 89
Table 5.—Combined industry—materials used, by kind, quantity, and cost, with per cent of increase: 1905 and 1900 ... 89
Table 6.—Combined industry—net value of products, with per cent of increase: 1905 and 1900 ... 90
The tin and terne dipping industry ... 90–94
Table 7.—Tin and terne dipping industry—comparative summary, with per cent of increase: 1905 and 1900 ... 90
Table 8.—Tin and terne dipping industry—active and idle establishments—capital: 1905 and 1900 ... 90
Table 9.—Tin and terne dipping industry—comparative summary, by states: 1905 and 1900 ... 91
Table 10.—Tin and terne dipping industry—materials used, by kind, quantity, and cost, with per cent of increase: 1905 and 1900 ... 91
Table 11.—Tin and terne dipping industry—comparative summary of products, by states: 1905 and 1900 ... 92
Table 12.—Tin plate, terne plate, and taggers tin produced, imported, exported, and retained for consumption: 1890 to 1905. 92
Table 13.—Tin and terne dipping industry—active and idle establishments—number, equipment, and daily capacity, by states: 1905 and 1900 ... 93
The black plate industry ... 94–96
Table 14.—Black plate industry—comparative summary, with per cent of increase: 1905 and 1900 ... 94

TIN AND TERNE PLATE—Continued. Page.
The black plate industry—Continued.
Table 15.—Black plate industry—active and idle establishments—capital: 1905 and 1900 ... 94
Table 16.—Black plate industry—comparative summary, by states: 1905 and 1900 ... 95
Table 17.—Black plate industry—materials used, by kind, quantity, and cost, with per cent of increase: 1905 and 1900 ... 95
Table 18.—Black plate industry—comparative summary of products, by states: 1905 and 1900 ... 95
Table 19.—Black plate industry—active and idle establishments—number, equipment, and capacity, by states: 1905 and 1900 ... 96
Table 20.—Tin and terne plate—detailed summary, by states: 1905 ... 96
Table 21.—Tin and terne plate—idle establishments—capital, capacity, and power: 1905 ... 97
COPPER, LEAD, AND ZINC, SMELTING AND REFINING ... 101–126
The combined industry ... 101–103
Table 1.—Copper, lead, and zinc, smelting and refining—comparative summary, by industries, with per cent of increase: 1905 and 1900 ... 101
Copper and lead, smelting and refining—quantity of principal products, with amount and per cent of increase: 1905 and 1900. 102
Copper smelting and refining ... 103–113
Table 2.—Copper smelting and refining—comparative summary, with per cent of increase: 1905 and 1900 ... 103
Table 3.—Copper smelting and refining—idle establishments: 1905 ... 103
Table 4.—Copper smelting and refining: 1890 ... 103
Table 5.—Production of copper in the United States: 1845 to 1904 ... 104
The industry, by states and territories ... 104
Table 6.—Copper smelting and refining—comparative summary, by states and territories: 1905 and 1900 ... 105
Table 7.—Copper smelting and refining—comparative summary of establishments, by location, east and west of the Mississippi river, with per cent of increase: 1905 and 1900 ... 105
Refining Lake Superior mineral: 1905 ... 106
Materials used ... 106
Table 8.—Copper smelting and refining—materials used, by kind, quantity, and cost, with number of establishments reporting: 1905 and 1900 ... 106
Table 9.—Copper smelting and refining—principal materials used, by kind and quantity, and by states and territories: 1905 and 1900 ... 106
Table 10.—Copper smelting and refining—establishments classified according to kind of materials used: 1905 and 1900. 107
Table 11.—Copper smelting and refining—salaries, wages, miscellaneous expenses, and cost of materials for establishments classified according to kind of materials used, with per cent which each item forms of total: 1905 and 1900 ... 108
Products ... 108
Table 12.—Copper smelting and refining—products, by kind, quantity, and value, with number of establishments reporting: 1905 and 1900 ... 108
Table 13.—Copper smelting and refining—principal products, by kind and quantity, and by states and territories: 1905 and 1900 ... 109
Process employed—smelting, refining, and smelting and refining ... 109
Table 14.—Copper smelting and refining—establishments classified according to process employed: 1905 and 1900 ... 110
Table 15.—Copper smelting and refining—salaries, wages, miscellaneous expenses, and cost of materials for establishments classified according to process employed, with per cent which each item forms of total: 1905 and 1900 ... 111
Gross and net values of products ... 111
Table 16.—Copper smelting and refining—establishments reporting gross and net values of products: 1905 ... 111
Table 17.—Copper smelting and refining—detailed summary, by states and territories: 1905 ... 112
Lead smelting and refining ... 113–122
Table 18.—Lead smelting and refining—comparative summary, with per cent of increase: 1905 and 1900 ... 113
Table 19.—Lead smelting and refining—idle establishments: 1905 ... 113
Table 20.—Lead smelting and refining: 1890 ... 114
Table 21.—Production of refined lead in the United States: 1873 to 1904 ... 114
Table 22.—Lead smelting and refining—production of refined lead, by states: 1905 and 1900 ... 114
The industry, by states ... 114
Table 23.—Lead smelting and refining—comparative summary, by states: 1905 and 1900 ... 114
Table 24.—Lead smelting and refining—comparative summary of establishments, by location, east and west of the Mississippi river: 1905 and 1900 ... 115
Table 25.—Lead smelting and refining—comparative summary of materials and products, net cost and value, in establishments, by location, east and west of the Mississippi river: 1905 and 1900 ... 116
Table 26.—Lead smelting and refining—statistics of Missouri smelters: 1890 to 1905 ... 116
Materials used ... 116
Table 27.—Lead smelting and refining—quantity of ore smelted and base bullion refined and desilverized, by states: 1905 and 1900 ... 116
Products ... 116
Table 28.—Lead smelting and refining—principal products, by kind, quantity, and value, with number of establishments reporting: 1905 and 1900 ... 117
Lead smelting and refining—quantity and value of principal products, with per cent of increase: 1905 and 1900 ... 117
Table 29.—Lead smelting and refining—principal products, by kind and quantity, and by states: 1905 and 1900 ... 118

COPPER, LEAD, AND ZINC, SMELTING AND REFINING—Continued. Page.
Lead smelting and refining—Continued.
Process employed—smelting, and smelting and refining ... 118
Table 30.—Lead smelting and refining—establishments classified according to process employed, with per cent of increase: 1905 and 1900 ... 119
Table 31.—Lead smelting and refining—comparative summary of materials and products, net cost and value, classified according to process employed: 1905 and 1900 ... 120
Gross and net values of products ... 120
Table 32.—Lead smelting and refining—establishments reporting gross and net values of products: 1905 ... 120
Table 33.—Lead smelting and refining—detailed summary, by states: 1905 ... 121
Zinc smelting ... 122–126
Table 34.—Zinc smelting—comparative summary, with per cent of increase: 1890 to 1905 ... 122
Table 35.—Zinc smelting—idle establishments: 1905 ... 122
Table 36.—Production of spelter in the United States: 1873 to 1904 ... 122
The industry, by states ... 123
Table 37.—Zinc smelting—comparative summary, by states: 1905 and 1900 ... 123
Table 38.—Zinc smelting—comparative summary of establishments, by location, east and west of the Mississippi river: 1905 and 1900 ... 123
Table 39.—Zinc smelting—comparative summary of establishments arranged according to location: 1905 and 1900 ... 124
Products ... 124
Table 40.—Zinc smelting—products, by kind, quantity, and value: 1905 and 1900 ... 125
Table 41.—Zinc smelting—detailed summary, by states: 1905 ... 125
AGRICULTURAL IMPLEMENTS ... 129–153
Table 1.—Comparative summary, with per cent of increase: 1850 to 1905 ... 129
The industry, by geographic divisions ... 131
Table 2.—Per cent distribution of establishments, capital, and value of products, with per cent of increase, by geographic divisions: 1905 and 1900 ... 131
The industry, by states ... 131
Table 3.—Comparative summary, by states and geographic divisions: 1905 and 1900 ... 131
Rank of the three states leading in value of products in 1905: 1850 to 1905 ... 133
The industry in cities ... 134
Table 4.—Summary for cities having a population in 1900 of 20,000 or over: 1905 ... 134
Products ... 134
Table 5.—Number and kind of principal agricultural implements manufactured, by states: 1905 ... 135
Table 6.—Kind and value of products, by states: 1905 ... 135
Table 7.—Comparative summary—number and kind of agricultural implements manufactured: 1870 to 1905 ... 136
Table 8.—Number of establishments reporting each kind of implement, with the total number manufactured: 1905 ... 137
Table 9.—Industries manufacturing agricultural implements as a minor product, with number of establishments and value of such products, by kinds: 1905 ... 138
Table 10.—Establishments manufacturing agricultural implements as a minor product, and value of such products, by states: 1905 ... 138
Power ... 139
Table 11.—Power—comparative summary, with per cent each kind is of the total: 1905 and 1900 ... 139
Patents in relation to agricultural implements ... 139
Table 12.—Patents granted to June 5, 1906 ... 139
Exports ... 139
Table 13.—Value of exports of agricultural implements: years ending June 30, 1900 to 1905 ... 139
Table 14.—Agricultural implements—detailed summary, by states: 1905 ... 142
Maps and diagrams
Map 1.—States having products valued at $100,000 and over: 1905 ... 133
Map 2.—States having products valued at $100,000 and over: 1900 ... 133
Diagram 1.—Comparative growth of the value of products, by geographic divisions: 1850 to 1905 ... 130
Diagram 2.—Growth of the total value of exports and of total value of exports to specified countries: 1890 to 1905 ... 140
ELECTRICAL MACHINERY, APPARATUS, AND SUPPLIES ... 157–221

Lighting fixtures ... 190
Table 13.—Electric light fixtures—value: 1905 and 1900 ... 190
Telephone apparatus ... 191
Table 14.—Telephones and telephone apparatus—number and value: 1905 ... 192
Telegraph apparatus ... 200
Table 15.—Telegraph apparatus—number and value: 1905 and 1900 ... 200
Insulated wires and cables ... 204
Table 16.—Insulated wires and cables—value: 1905 and 1900 ... 204
Conduits ... 206
Table 17.—Electric conduits—value: 1905 and 1900 ... 206
Annunciators and clocks ... 207
Table 18.—Annunciators—number and value: 1905 and 1900 ... 207
Table 19.—Electric clocks and time mechanisms—number and value: 1905 and 1900 ... 208
Rheostats and resistances ... 208
Table 20.—Rheostats and resistances—number and value: 1905 ... 208
Heating apparatus ... 210
Table 21.—Electric heating, cooking, and welding apparatus—number and value: 1905 ... 210
Fuses and lightning arresters ... 211
Table 22.—Fuses and lightning arresters—number and value: 1905 and 1900 ... 212
Electric measuring instruments ... 213
Table 23.—Electric measuring instruments—number and value: 1905 and 1900 ... 213
Circuit fittings ... 214
Table 24.—Circuit fittings of all kinds—number and value: 1905 ... 214
All other products ... 215
Table 25.—All other products—value: 1905 and 1900 ... 215
Custom work and repairing ... 217
Table 26.—Amount received for custom work and repairing: 1905 and 1900 ... 217
Table 27.—Electrical machinery, apparatus, and supplies—detailed summary, by states: 1905 ... 218
Illustrations: Facing page.
Building up the armature of a large electric generator ... 160
Constructing a large alternating current transformer ... 160
Three 500-kilowatt turbine direct connected generators installed in a railroad repair shop ... 162
Factory equipped with steam turbine dynamo electric units for supplying light and power ... 162
Steam turbine generator sets in engine room of a Hudson river steamboat ... 164
Twenty-four hundred kilowatt steam turbine generator at a coal mine in Kentucky ... 164
Winding armatures for electric generators ... 166
Railroad shop with tools equipped with motors on multiple voltage system ... 166
Floor of electric factory for assembling electric railway motors ... 168
Keyboard cables for telephone exchange. (Skeleton of switchboard section in the rear.) ... 192
Telephone switchboard, showing rear view of subscribers' sections, with multiple cables, answering jack cables, cord circuit cables, and relays ... 194

METAL WORKING MACHINERY ... 225–236
Table 1.—Metal working machinery—value of products, by states, with per cent of total and per cent of increase: 1905 and 1900. 225
Table 2.—Exports and imports of iron and steel manufactures and total machinery, and exports of metal working machinery: 1900 to 1904 ... 226
Table 3.—Metal working machinery—value of products, by class of machines, with per cent each class is of the total and per cent of increase: 1905 and 1900 ... 227
Table 4.—Production of lathes, including automatic, hand, engine, turret, and semiautomatic, by states: 1905 and 1900 ... 227
Table 5.—Production of milling machines, including all machines using a milling cutter, by states: 1905 and 1900 ... 227
Table 6.—Production of boring and drilling machinery, by states: 1905 and 1900 ... 228
Table 7.—Production of stamping, flanging, and forming machines for plate and sheet metal, by states: 1905 and 1900 ... 228
Table 8.—Production of pneumatic hand machines: 1905 and 1900 ... 228
Table 9.—Production of planers, including plate edge planers, by states: 1905 and 1900 ... 228
Table 10.—Production of punching and shearing machines, by states: 1905 and 1900 ... 229
Table 11.—Production of grinding and polishing machinery, by states: 1905 and 1900 ... 229
Table 12.—Production of boring and turning mills, or vertical lathes, by states: 1905 and 1900 ... 229
Table 13.—Production of bolt, nut, and pipe threading and tapping machines, by states: 1905 and 1900 ... 229
Table 14.—Production of slotters and shapers, by states: 1905 and 1900 ... 230

METAL WORKING MACHINERY—Continued. Page.
Table 15.—Production of hammers—steam, power, and drop—by states: 1905 and 1900 230
Table 16.—Production of forging machines, by states: 1905 and 1900 230
Table 17.—Production of riveting machines, by states: 1905 and 1900 230
Table 18.—Production of bending and straightening rolls, by states: 1905 and 1900 230
Table 19.—Production of sawing machines, by states: 1905 and 1900 231
Table 20.—Production of "all other metal working machinery," by states: 1905 231
Development of the industry 231–236
Foreign use of American tools 231
Specialization in manufacture 232
High speed steel 232
Speed adjustment 232
Portable tools 233
Automatics 233
New grinding process 235
Interchangeable tools 235
Illustrations: Facing page.
Lathe arranged for driving by a constant-speed belt 232
Rear view of lathe driven by electric motor 232
Multiple-spindle automatic screw machine 234
Automatic screw machine for working bars 6 inches in diameter 234
Automatic screw machine with magazine attachment 236
Automatic screw machine 236

MUSICAL INSTRUMENTS, ATTACHMENTS, AND MATERIALS 239–266
The combined industry 239–242
Table 1.—Musical instruments, attachments, and materials—comparative summary, with per cent of increase: 1860 to 1905. 239
Table 2.—Musical instruments, attachments, and materials—summary, by industries, with per cent of total: 1905 240
Table 3.—Musical instruments, pianos and organs—products of each industry, by kind, quantity, and value: 1905 240
Table 4.—Musical instruments, attachments, and materials—comparative summary, by selected states: 1880 to 1905 241
Table 5.—Musical instruments, attachments, and materials—value of exports and imports compared with value of domestic production: 1870 to 1905 242
Pianos 242–245
Table 6.—Pianos, including piano players and attachments—kind and value, with per cent of total and per cent of increase: 1905 and 1900 243
Table 7.—Pianos, upright and grand—number and value, with per cent of total value, by states: 1905 and 1900 243
Organs 245–248
Table 8.—Organs—kind and value, with per cent of total and per cent of increase: 1905 and 1900 245
Table 9.—Reed organs—number and value, with per cent of total value, by states: 1905 and 1900 245
Table 10.—Pipe organs—number and value, with per cent of total value, by states: 1905 and 1900 247
Self-playing and street pianos and organs, and piano players and attachments 248, 249
Table 11.—Self-playing and street pianos and organs, and piano players and attachments—kind and value, with per cent of total and per cent of increase: 1905 and 1900 248
Table 12.—Piano players and piano playing attachments—number and value, with per cent of total value: 1905 and 1900 248
Table 13.—Self-playing pianos and organs—number and value, with per cent of total value: 1905 and 1900 248
Piano and organ materials 250, 251
Table 14.—Piano and organ materials—value of products, by states: 1905 250
Table 15.—Piano materials and parts—distribution of value, by kind: 1905 250
Table 16.—Organ materials and parts—distribution of value, by kind: 1905 251
Table 17.—Musical instruments, pianos—detailed summary, by states: 1905 252
Table 18.—Musical instruments, organs—detailed summary, by states: 1905 256
Table 19.—Musical instruments, piano and organ materials—detailed summary, by states: 1905 258
Table 20.—Musical instruments and materials, not specified—detailed summary, by states: 1905 260
Phonographs and graphophones 264–266
Table 21.—Phonographs and graphophones—comparative summary, with per cent of increase: 1905 and 1900 264
Table 22.—Phonographs and graphophones—products, by kind and value, with per cent of total and per cent of increase: 1905 and 1900 264
Table 23.—Phonographs and graphophones—detailed summary, by states: 1905 266
AUTOMOBILES 269–285
Table 1.—Comparative summary, with per cent of increase: 1905 and 1900 269
Table 2.—Miscellaneous expenses: 1905 and 1900 269
Table 3.—Comparative summary, by states: 1905 and 1900 270
Table 4.—Number and value of automobiles, by class and kind of power used: 1905 272
Table 5.—Average value of automobiles, by class and kind of power used: 1905 273
Table 6.—Rank of leading states with respect to principal items of inquiry: 1905 and 1900 273
Table 7.—Summary for cities having a population in 1900 of at least 20,000: 1905 274
Table 8.—Power—comparative summary: 1905 and 1900 274
Automobiles as a minor product 274, 275

AUTOMOBILES—Continued. Page.
Allied industries ... 275
Automobile bodies and parts ... 275
Table 9.—Summary—automobiles and automobile bodies and parts: 1905 ... 275
Rubber and elastic goods ... 275
Table 10.—Rubber and elastic goods—comparative summary: 1905 and 1900 ... 275
Imports and exports ... 275–277
Table 11.—Value of exports of automobiles and automobile parts, for years ending June 30: 1902 to 1905 ... 276
Table 12.—Automobiles and automobile parts imported and entered for consumption during the fiscal years ending June 30: 1901 to 1905 ... 276
Statistical summary ... 277
Historical and descriptive ... 277–280
The modern automobile ... 277
Steam motors ... 278
Petrol motors ... 278
Electric motors ... 279
Frame, wheels, and body ... 279
Table 13.—Automobiles—detailed summary, by states: 1905 ... 282
BICYCLES AND TRICYCLES ... 289–297
Table 1.—Comparative summary, with per cent of increase and decrease: 1890 to 1905 ... 289
Production ... 289
Table 2.—Number and value of different kinds of products, including those produced as secondary products: 1905 and 1900 ... 289
Table 3.—Comparative summary, active establishments, by states, with increase and decrease: 1890 to 1905 ... 290
Table 4.—Comparative summary, by states: 1905 and 1900 ... 291
Exports ... 291
Table 5.—Value of exports of bicycles and tricycles, and parts thereof: 1896 to 1905 ... 291
Historical and descriptive ... 291, 292
Table 6.—Bicycles and tricycles—detailed summary, by states: 1905 ... 294
CARRIAGES AND WAGONS ... 301–327
Table 1.—Comparative summary, with per cent of increase: 1890 to 1905 ... 301
The industry, by states and territories ... 301
Table 2.—Comparative summary, by states, territories, and geographic divisions: 1905 and 1900 ... 302
The industry in cities ... 304
Materials used ... 304
Table 3.—Materials used, by kind, quantity, and cost, with per cent of increase: 1905 and 1900 ... 304
Products ... 304
Table 4.—Products, by kind, quantity, and value, with per cent of increase: 1905 and 1900 ... 304
Table 5.—Products, by kind, quantity, and value—comparative summary, by states and territories: 1905 and 1900 ... 305
Exports and imports ... 307
Exports and imports of carriages and wagons, and parts thereof: 1900 to 1905 ... 307
Carriage and wagon materials ... 307
Table 6.—Carriage and wagon materials—comparative summary: 1890 to 1905 ... 307
Table 7.—Carriages and wagons—detailed summary, by states and territories: 1905 ... 310
SHIPBUILDING ... 331–353
The combined industry ... 331–335
Table 1.—Comparative summary, with per cent of increase: 1850 to 1905 ... 331
Branches of the industry ... 332
Table 2.—Comparative summary, by branches: 1905 and 1900 ... 332
Materials used ... 333
Table 3.—Materials used, by kind and cost, with per cent of total: 1890 to 1905 ... 333
Products ... 333
Table 4.—Products, by kind and value, with per cent of total: 1880 to 1905 ... 333
Table 5.—Rank, according to capital and value of products, of states having products valued at one million dollars and over for 1905: 1880 to 1905 ... 334
The industry by watershed districts ... 334
Table 6.—Summary, by watershed districts, with per cent of total: 1905 ... 334
Table 7.—Comparative summary for the Great Lakes district, by branches, with per cent of increase: 1905 and 1900 ... 335
Governmental establishments ... 335
Table 8.—Governmental establishments—comparative summary, with per cent of increase: 1905 and 1900 ... 335
Vessels launched, small boats, and repair work ... 335–343
Vessels of five tons and over ... 336
Table 9.—Number, tonnage, and value of vessels of five tons and over launched by private shipyards, with per cent of increase: 1880 to 1905 ... 336
Table 10.—Number, tonnage, and value of vessels of five tons and over launched during 1904 by all establishments, classified according to service ... 337
Table 11.—Steel vessels of 1,000 tons and over for the United States Navy launched during 1904 by private shipyards ... 337
Table 12.—Steel vessels of 1,000 tons and over launched during 1904 by Government shipyards ... 337

SHIPBUILDING—Continued. Page.
Vessels of five tons and over—Continued.
Table 13.—Net tonnage of merchant vessels of five tons and over launched during 1904 by private shipyards, classified according to kind of trade, by geographic divisions ... 337
Table 14.—Number, tonnage, and value of vessels of five tons and over launched by private shipyards, classified according to motive power, with per cent of increase: 1880 to 1905 ... 338
Table 15.—Number, tonnage, and value of vessels of five tons and over launched during 1904 by private shipyards, classified according to motive power, by watershed districts ... 339
Table 16.—Number, tonnage, and value of steel and wooden vessels of five tons and over launched by private shipyards on the Great Lakes, with per cent of increase: 1905 and 1900 ... 339
Table 17.—Rank of principal states according to value of vessels of five tons and over launched by private shipyards: 1905 and 1900 ... 339
Table 18.—Rank of principal states according to value of each class of vessels of five tons and over launched during 1904 by private shipyards ... 339
Steam and other power vessels ... 340
Table 19.—Value of iron and steel and wooden steam and other power vessels of five tons and over launched by private shipyards, with per cent of total: 1890 to 1905 ... 340
Table 20.—Number, gross and net tonnage, and value of power vessels, other than steam, of five tons and over, launched during 1904 by private shipyards, by states ... 340
Barges ... 340
Table 21.—Value of iron and steel and wooden barges, with per cent of total: 1890 to 1905 ... 340
Table 22.—Number, gross and net tonnage, and value of barges, by states: 1905 and 1900 ... 341
Sail vessels ... 341
Table 23.—Value of iron and steel and wooden sail vessels of five tons and over launched by private shipyards, with per cent of total: 1890 to 1905 ... 341
Table 24.—Number, gross and net tonnage, and value of sail vessels of five tons and over launched by private shipyards, by states: 1905 and 1900 ... 341
Canal boats ... 341
Table 25.—Number, gross and net tonnage, and value of canal boats, by states: 1905 and 1900 ... 342
Small boats ... 342
Table 26.—Number and value of boats under five tons, by states: 1905 and 1900 ... 342
Repair work ... 343
Table 27.—Value of repair work reported by private and Government shipyards, with per cent of total and per cent of increase: 1905 and 1900 ... 343
Table 28.—Value of repair work reported by private shipyards, by states: 1890 to 1905 ... 343
Equipment of shipyards ... 343–346
Table 29.—Number of private shipyards and value of repair work, together with number of private shipyards reporting dry dock or marine railway equipment and value of their repair work: 1905 ... 344
Dry docks ... 344
Table 30.—Number and kind of dry docks in private and Government shipyards, classified according to dimensions, by states and geographic divisions: 1905 ... 344
Number and kind of dry docks at each naval station in the United States: 1905 ... 345
Illustration—Floating dry dock *Dewey* ... Facing page.. 344
Marine railways ... 345
Table 31.—Number and lifting capacity of marine railways, classified according to dimensions and lifting capacity, by states and geographic divisions: 1905 ... 346
Power ... 347
Table 32.—Number of private establishments reporting power owned or rented, and amount of each kind of power available for use, by branches: 1905 and 1900 ... 347
Table 33.—Iron and steel shipbuilding—detailed summary, by states: 1905 ... 348
Table 34.—Wooden shipbuilding, including boat building—detailed summary, by states: 1905 ... 350
THE STEAM AND STREET RAILROAD CAR INDUSTRY ... 357–393
Steam railroad cars and repairs ... 357–385
Table 1.—Cars, steam railroad, and steam railroad repair shops—comparative summary, with per cent of increase: 1890 to 1905 ... 357
Table 2.—Cars, steam railroad, and steam railroad repair shops—comparative summary, by industries, with per cent of increase: 1890 to 1905 ... 358
Products ... 358
Table 3.—Number, kind, and value of steam railroad cars built by all establishments: 1905 and 1900 ... 359
Table 4.—Cars, steam railroad, and steam railroad repair shops—comparative summary of products, by kind, quantity, and value, for the United States and ten leading states: 1905 and 1900 ... 362
Cars, steam railroad ... 364
Table 5.—Cars, steam railroad—summary, by geographic divisions, 1905 ... 364
Table 6.—Cars, steam railroad—comparative summary, by states: 1890 to 1905 ... 365
Products ... 366
Table 7.—Cars, steam railroad—number and value of cars built, distributed according to kind: 1905 and 1900 ... 366
Exports ... 367
Table 8.—Value of exports of steam railroad passenger and freight cars, and parts of same, by countries: 1880 to 1905. 367

THE STEAM AND STREET RAILROAD CAR INDUSTRY—Continued. Page.
Steam railroad cars and repairs—Continued.
Steam railroad repair shops ... 367
Table 9.—Steam railroad repair shops—summary, by geographic divisions: 1905 ... 367
Table 10.—Steam railroad repair shops—comparative summary, by states and territories: 1890 to 1905 ... 368
Table 11.—Cars, steam railroad, not including operations of railroad companies—detailed summary, by states: 1905 ... 371
Table 12.—Cars and general shop construction and repairs by steam railroad companies—detailed summary, by states and territories: 1905 ... 374
Street railroad cars and repairs ... 386–393
Table 13.—Cars, street railroad, and street railroad repair shops—comparative summary, with per cent of increase: 1890 to 1905 ... 386
Table 14.—Cars, street railroad, and street railroad repair shops—comparative summary, by industries, with per cent of increase: 1890 to 1905 ... 386
Products ... 387
Table 15.—Number, kind, and value of street railroad cars built by all establishments: 1905 ... 387
Street railroad repair shops ... 388
Table 16.—Street railroad repair shops—summary, by geographic divisions: 1905 ... 388
Table 17.—Cars, street railroad, not including operations of railroad companies—detailed summary, by states: 1905 ... 389
Table 18.—Cars and general shop construction and repairs by street railroad companies—detailed summary, by states: 1905. 390
CHEMICALS AND ALLIED PRODUCTS ... 397–512
Scope of the census ... 397–403
Table 1.—Chemicals and allied products—comparative summary, with amount and per cent of increase: 1905 and 1900 ... 398
Table 2.—Comparative summary, by industries: 1905 and 1900 ... 398
Table 3.—Increase and per cent of increase in the separate industries: 1900 to 1905 ... 399
Table 4.—Number of establishments, by states and territories, with increase and rank: 1905 and 1900 ... 399
Table 5.—Quantity and cost of materials used, with amount and per cent of increase, and average cost per unit: 1905 and 1900 ... 400
Table 6.—Quantity and value of products, with amount and per cent of increase: 1905 and 1900 ... 401
Table 7.—Products consumed in establishments where manufactured, with amount and per cent of increase: 1905 and 1900. 403
Class I. A.—Sulphuric, nitric, and mixed acids ... 403–417
Table 8.—Sulphuric, nitric, and mixed acids—comparative summary, with amount and per cent of increase: 1905 and 1900. 404
Sulphuric acid ... 404
Table 9.—Sulphuric acid—number of establishments and quantity and value of products: 1870 to 1905 ... 404
Table 10.—Sulphuric acid—increase and per cent of increase in quantity and value of products: 1870 to 1905 ... 404
Table 11.—Total quantity and value of sulphuric acid, by grades: 1890 to 1905 ... 405
Table 12.—Sulphuric acid—number of establishments, by states and territories: 1905 and 1900 ... 405
Table 13.—Sulphuric acid—quantity of products, by geographic divisions: 1905 and 1900 ... 406
Table 14.—Pyrites produced in, and imported into, the United States: 1895 to 1904 ... 407
Table 15.—Sulphur imported and entered for consumption in the United States: 1895 to 1904 ... 407
Table 16.—Tons of real sulphuric acid and of chamber acid theoretically produced by a ton of each of the minerals specified ... 407
Contact process plants ... 410
Chamber process plants ... 411
Table 17.—Quantity of sulphuric acid consumed for specific purposes: 1900 ... 411
Nitric acid ... 412
Table 18.—Nitric acid—quantity and value of products: 1905 and 1900 ... 412
Table 19.—Nitric acid—number of establishments, by states: 1905 and 1900 ... 412
Table 20.—Results of nitric acid distillation obtained with the first two Valentiner vacuum apparatus installed in the United States: 1904 ... 414
Mixed acids ... 415
Table 21.—Mixed acids—quantity and value of products: 1905 and 1900 ... 415
Table 22.—Mixed acids—number of establishments, by states: 1905 and 1900 ... 415
Table 23.—Mixed acids—quantity of products, by geographic divisions: 1905 and 1900 ... 416
Percentage composition of various mixed acids ... 416
Class I. B.—Other acids ... 417–420
Table 24.—"Other acids"—comparative summary, with amount and per cent of increase: 1905 and 1900 ... 417
Muriatic acid ... 417
Table 25.—Muriatic acid—quantity and value of products: 1905 and 1900 ... 417
Table 26.—Muriatic acid—number of establishments, by states: 1905 and 1900 ... 418
Table 27.—Muriatic acid—quantity of products, by geographic divisions: 1905 and 1900 ... 418
Table 28.—Muriatic acid produced with Cellarius jars during a twelve months' run ... 418
Acetic acid ... 418
Table 29.—Acetic acid—quantity and value of products: 1905 and 1900 ... 418
Table 30.—Acetic acid—number of establishments, by states: 1905 and 1900 ... 419
All other acids ... 419
Table 31.—Minor acids—number of establishments and quantity and value of products: 1905 and 1900 ... 419
Table 32.—Acids—imports for consumption: 1891 to 1905 ... 419
Bibliography ... 420

CHEMICALS AND ALLIED PRODUCTS—Continued. Page.
Class II.—Sodas ... 420–425
Table 33.—Sodas—comparative summary, with amount and per cent of increase: 1905 and 1900 ... 421
Table 34.—Sodas—quantity and value, with per cent of increase: 1880 to 1905 ... 421
Table 35.—Sodas—quantity and value of products, with amount and per cent of increase: 1890 to 1905 ... 421
Table 36.—Sodas—number of establishments, by states: 1905 and 1900 ... 422
Table 37.—Sodas—value of products, by geographic divisions: 1905 and 1900 ... 422
Table 38.—World's production of sodas: 1850 to 1902 ... 423
Table 39.—Sodas—imports entered for consumption: 1891 to 1905 ... 425
Bibliography ... 425
Class III.—Potashes ... 425–428
Table 40.—Potashes—quantity and value of products: 1850 to 1905 ... 426
Table 41.—Imports of potashes, ashes (wood) and lye of, and beet root ashes, entered for consumption; and domestic exports of potashes and pearlashes: 1891 to 1905 ... 428
Class IV.—Alums ... 428–430
Table 42.—Alums—comparative summary, with amount and per cent of increase: 1905 and 1900 ... 428
Table 43.—Alums—quantity and value: 1880 to 1905 ... 428
Table 44.—Kinds of alum—quantity and value of products: 1905 and 1900 ... 429
Table 45.—Alums—number of establishments, by states: 1905 and 1900 ... 429
Table 46.—Alums—value of products, by states: 1905 and 1900 ... 429
Table 47.—Alums, cryolite, and bauxite—imports for consumption: 1891 to 1905 ... 430
Class V.—Coal tar products ... 430–432
Table 48.—Coal tar products—comparative summary, with amount and per cent of decrease: 1905 and 1900 ... 430

LETTER OF TRANSMITTAL.

DEPARTMENT OF COMMERCE AND LABOR,
BUREAU OF THE CENSUS,
Washington, D. C., May 14, 1908.

SIR:

I have the honor to transmit herewith Part IV of the Report on Manufactures for the census of 1905. This census was taken in conformity with the act of Congress of March 6, 1902, and the statistics cover the calendar year ending December 31, 1904.

This volume is a compilation of the bulletins for a number of the leading industries of the United States, which were published as rapidly as the compilation of the data was finished. The monographs are bound together, because it is the only way they can be permanently preserved and made convenient for general reference. The statistics contained in these reports are combined with those for all other industries, thus giving the totals for all branches of manufactures in the United States and in each state and territory, which are published in Parts I and II of the census of 1905. The fieldwork, the compilation of the statistics, and the preparation of the text have been done by the regular force of the Office, working under the supervision of Mr. William M. Steuart, chief statistician for manufactures.

Very respectfully,

S. N. D. North
Director.

Hon. OSCAR S. STRAUS,
Secretary of Commerce and Labor.

IRON AND STEEL

IRON AND STEEL.

By Story B. Ladd.

This report presents the statistics of the iron and steel industry for the census of manufactures of 1905. The period covered is the calendar year 1904, or the business year of the establishment reporting which most nearly conforms to this, and ends before January 1, 1905.

In drawing comparisons between the figures of the different censuses it should be borne in mind that the interval between the present census and that of 1900 is but one-half of that for prior census periods.

It should also be specially noted that the iron and steel industry in 1904 was seriously affected by the general business depression which began in the first half of 1903 and continued until August and September, 1904. The iron and steel production during the year 1904 was in many lines less than in 1903 and 1902, the increased production resulting from the revival in the fall of the year not being sufficient to offset the losses during the earlier months. On the other hand, each of the prior censuses from 1870 to 1900, inclusive, which is presented in this report in comparison with 1905, was for a year of industrial activity and prosperity, a year of advancement and growth. The census of 1870 was taken for a year of increasing production, the crest of which, measured by pig iron production, was reached in 1873; the crest of the wave of increase of 1880 was reached in 1883; 1890 was at the summit of a period of business activity and growth; and the period of increasing production witnessed in 1900 did not receive a check until 1903. Likewise, the iron and steel production for the calendar year 1905 was abnormally and phenomenally large and the industry uniformly prosperous. The Census report therefore presents under cover of 1905, which was an active and prosperous year, the statistics for a year of partial depression and curtailment, in comparison with prior census years of growth and prosperity.

The statistics relate only to establishments which operate blast furnaces, steel works and rolling mills, and forges and bloomeries. Establishments manufacturing iron blooms, billets, and hammered bar iron direct from iron ore or from pig iron, scrap iron, or steel are classified as forges and bloomeries only when the products are made for sale and not for consumption in a rolling mill department of the producing plant. In the early years of the iron and steel industry the forges and bloomeries were an important feature, but they have been steadily declining, and at the census of 1905 the few remaining bloomeries are included in the statistics for steel works and rolling mills except when shown separately for comparative purposes with former years.

The blast furnace products include all kinds of pig iron, spiegeleisen, ferromanganese, and ferrosilicon, whether cast or used in a molten condition in Bessemer converters, open-hearth furnaces, cupolas, etc., and castings made direct from the furnace. The products of steel works and rolling mills embrace steel ingots and direct steel castings and all hot rolled or forged iron or steel. Many mills carry the manufacture of the primary rolling mill products through to more highly finished forms, such as nails, spikes, bolts, nuts, and wire, and in some cases products of this kind constitute the bulk of the output of the establishment. In such cases the statistics presented are those of the primary rolling mill products, the enhanced value due to the further manufacture into more highly finished forms being handled as a separate factor. The gross ton (2,240 pounds) is used throughout the report except for coke, which is in short tons (2,000 pounds).

At the census of 1880 the capital and labor employed in mining iron ore and coal, in coke making, quarrying limestone, charcoal burning, etc., were included in the capital invested and labor employed in the production of pig iron where the mines, ovens, quarries, or kilns were owned or operated by the blast furnace establishments. The cost of materials reported was nevertheless, apparently, the cost at the furnace, and hence the figures of cost for 1880 involve a duplication to this extent. The statistics for 1890, 1900, and 1905 for the blast furnace industry relate only to the manufacture of pig iron, and do not, as a rule, include details for any of these related industries.

The industry is discussed under the following heads:

The iron and steel industry as a whole.
The electrothermic metallurgy of iron and steel.
Blast furnaces.
Steel works and rolling mills.
Forges and bloomeries.

THE IRON AND STEEL INDUSTRY.

Table 1 shows the general statistics for the iron and steel industry as a whole for the census years 1870 to 1905, with the percentage of increase or decrease for each period. In 1870 active establishments were not separated from idle, but for each of the later years only active establishments are included.

TABLE 1.—IRON AND STEEL—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1870 TO 1905.

	CENSUS.					PER CENT OF INCREASE.			
	1905[1]	1900	1890	1880	1870	1900 to 1905	1890 to 1900	1880 to 1890	1870 to 1880
Number of establishments	[2] 606	[2] 669	719	792	[2] 808	[4] 9.4	[4] 7.0	[4] 9.2	[4] 2.0

Salaries	$20,758,412	$11,741,788	[6] $6,462,286	(7)	(7)	76.8	81.7	.....	.....
Wage-earners, average number	242,740	222,607	171,181	140,798	77,555	9.0	30.0	21.6	81.5
Total wages	$141,439,906	$120,836,338	$89,273,956	$55,451,510	$40,514,981	17.1	35.4	61.0	36.9
Men 16 years and over	239,383	219,635	168,943	133,023	75,037	9.0	30.0	27.0	77.3
Wages	$140,545,610	$120,157,007	$88,840,642	(7)	(7)	17.0	35.3	.....	.....
Women 16 years and over	1,455	1,071	58	45	82	35.9	1,746.6	28.9	45.1
Wages	$441,967	$266,888	$17,106	(7)	(7)	65.6	1,460.2	.....	.....
Children under 16 years	1,902	1,901	2,180	7,730	2,436	0.1	[4] 12.8	[4] 71.8	217.3
Wages	$452,329	$412,443	$416,208	(7)	(7)	9.7	[4] 0.9	.....	.....
Miscellaneous expenses	$47,164,970	$32,274,100	$18,214,948	(8)	(8)	46.1	77.2	.....	.....
Cost of materials used	$620,171,881	$522,431,701	$327,272,845	$191,271,150	$135,526,132	18.7	59.6	71.1	41.1
Value of products [9]	$905,854,152	$804,034,918	$478,687,519	$296,557,685	$207,208,696	12.7	68.0	61.4	43.1
Tons of product [10]	34,844,933	29,507,860	16,264,478	6,486,733	3,263,585	18.1	81.4	150.7	98.8

[1] Exclusive of the statistics of 6 establishments engaged primarily in the manufacture of other products. These establishments made 4,184 tons of steel castings, valued at $347,264.
[2] Includes 1 penal institution, the statistics for which are not included in the detailed summary.
[3] Includes idle establishments which were not reported separately in 1870.
[4] Decrease.
[5] Includes value of rented property—1905, $12,106,619; 1900, $16,968,821; 1890, $8,273,058.
[6] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[7] Not reported separately.
[8] Not reported.
[9] Includes value of miscellaneous products for which tonnage was not reported.
[10] Gross tons of 2,240 pounds.

In 1870 the United States had a population of 38,558,371, and the iron and steel industry a product of 3,263,585 tons, or an average of 0.0846 of a ton of product per unit of population. In 1880 the iron and steel tonnage per unit of population had increased to 0.1293 of a ton; in 1890 it was 0.2584 of a ton; in 1900, 0.3883 of a ton; and in 1904, on the basis of the estimate of population of continental United States, it was 0.4288 of a ton. Thus the iron and steel industry not only keeps pace with the growth in population, but shows an increase per unit of population during the decade of 1870 to 1880 of 52.8 per cent; for the decade ending in 1890, of 99.8 per cent; for the decade ending in 1900, of 50.3 per cent; and for the five years 1900 to 1905, of 10.7 per cent.

The number of establishments has steadily decreased at each succeeding census, falling from 808 in 1870 to 606 in 1905, while the capital invested has increased nearly sevenfold and the value of products more than threefold. This shows strikingly the concentration that has marked the development of the industry during this period of thirty-five years. To a small extent the decrease in number of establishments in 1905, as compared with 1900, is due to the fact that in a few cases one report was made for two or more plants under the same ownership and within the same municipality, whereas in 1900 separate reports were made for the different plants.

It will be noted that the increase in capital is apparently out of proportion to the growth of the industry in other particulars. The reported capital invested in 1905 exceeds that of 1900 by $358,159,356, or 60.7 per cent; whereas the increase in wage-earners, wages paid, cost of materials, and value and quantity of products all fall within a range of from 9 to 19 per cent. This difference is in part explained by the depression in the iron and steel industry prevailing during the early part of the census year, which restricted production, labor, and operating expense. The capital invested in 1870 shows an average per ton of product of $37.31; in 1880 it was $32.36; in 1890, $25.46; and in 1900, $20.01. At the present census the invested capital as reported shows an average of $27.23 per ton of product. Manifestly, if the law of progress deduced from these returns holds true—namely, a steady advance in the earning power of capital from decade to decade through the use of improved appliances and methods—the capital invested per ton of product should, with full production, be less than that of former years, whereas it exceeds that of 1900 and 1890. The large increase in capital is due in part to the fact that, in the case of some of the corporations, the capital reported as invested in land, buildings, machinery, etc., and live capital, is stock capital as carried on their books, this being the only thing possible to report under the circumstances. But in the case of a corporation formed by the aggregation of a number of plants which have been turned over to the new company for stock considerations, such book accounts necessarily represent more than actual cash investments.

Attention is called to the fact that the number of children employed is substantially the same as in 1900 (except by one) and has not increased with the growth of this industry. In 1890 the average number of children under 16 years employed was 1.3 per cent of all wage-earners; in 1900 they constituted nine-tenths of 1 per cent; and in 1905 they formed eight-tenths of 1 per cent. The 1880 and 1870 figures include children

employed in coal mining, etc., in conjunction with blast furnace operations, and hence are not comparable.

Table 2 shows the leading statistics of the iron and steel industry for 1905, by states, in comparison with like statistics of the states or territories for 1880, 1890, and 1900. In the census years of 1900 and 1905 there were no territories which produced pig iron, steel, or rolling mill products.

As these statistics are the combined statistics for blast furnace establishments and steel works and rolling mills, which are separately considered in later tables, it is necessary to group under "all other states" such states as have establishments owned by less than three organizations in either branch of the industry, in order that the operations of individual establishments may not be deducible by comparison of the different tables.

TABLE 2.—IRON AND STEEL—COMPARATIVE SUMMARY, BY STATES: 1880 TO 1905.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.

[1] Includes value of rented property—1905, $12,106,619; 1900, $16,968,821; 1890, $8,273,058.
[2] Exclusive of steel castings to the value of $347,264, made by establishments engaged primarily in the manufacture of other products.
[3] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Not reported.
[6] Included in "all other states", in 1900 and 1905.
[7] Included in "all other states" in 1905.

[1] Included in "all other states" in 1905.
[2] Included in "all other states" in 1890 and 1905.
[3] Includes establishments distributed as follows: Colorado, 2; Connecticut, 9; Georgia, 5; Kansas, 1; Kentucky, 9; Maine, 1; Maryland, 9; Massachusetts, 6; Minnesota, 1; Missouri, 6; Oregon, 1; Rhode Island, 4; Tennessee, 15; Texas, 1; Washington, 1; West Virginia, 15.
[4] Includes establishments distributed as follows: Colorado, 3; Connecticut, 8; Kansas, 1; Kentucky, 8; Maine, 1; Massachusetts, 8; Minnesota, 3; Missouri, 7; North Carolina, 2; Oregon, 1; Rhode Island, 1; Washington, 1; Wyoming, 1.
[5] Includes establishments distributed as follows: Colorado, 2; Iowa, 1; Maine, 2; Minnesota, 1; New Hampshire, 1; North Carolina, 1; Oregon, 1; Rhode Island, 1; Texas, 1; Washington, 1; Wyoming, 1.
[6] Includes establishments distributed as follows: Colorado, 1; District of Columbia, 1; Kansas, 2; Maine, 3; Nebraska, 1; New Hampshire, 2; North Carolina, 9; Oregon, 1; Rhode Island, 1; Vermont, 2; Wyoming, 1.

Pennsylvania, Ohio, and Illinois were the leading states in 1905, as well as in 1900 and 1890. Pennsylvania produced 52 per cent of the value of all iron and steel products in 1905, as against 54 per cent in 1900, and 55.3 per cent in 1890; Ohio, 16.9 per cent in 1905, 17.3 per cent in 1900, and 13.6 per cent in 1890; and Illinois, 9.6 per cent in 1905, 7.5 per cent in 1900, and 8.1 per cent in 1890. The next state in rank, New York, produced 3.3 per cent of the products.

Of the capital invested in the iron and steel industry, Pennsylvania reported 49.8 per cent in 1905 and 54.5 per cent in 1900; Ohio, 13.8 per cent in 1905 and 14.6 per cent in 1900; and Illinois, 6.2 per cent in 1905 and 7.3 per cent in 1900.

Pennsylvania employed 51.4 per cent of all wage-earners in the industry in 1905 and 49.8 per cent in 1900; Ohio, 13.7 per cent in 1905 and 15.1 per cent in 1900; and Illinois, 7.6 per cent in 1905 and 7.5 per cent in 1900. In the matter of wages, Pennsylvania contributed 51.7 per cent of all wages in 1905 and 51.2 per cent in 1900; Ohio, 15.6 per cent in 1905 and 16.3 per cent in 1900; Illinois, 8.1 per cent in 1905 and 8 per cent in 1900. In cost of materials used Pennsylvania's share of the total was 52.3 per cent in 1905 and 54.2 per cent in 1900; that of Ohio, 17.8 per cent in 1905 and 17.5 per cent in 1900; and that of Illinois, 9.3 per cent in 1905 and 8 per cent in 1900.

As a combination of the statistics of these 3 leading states was made in prior reports, a like presentation will be given. The combined capital invested at the census of 1905 was $662,405,541, or 69.8 per cent of the total capital, compared with $451,819,450, or 76.5 per cent of the total in 1900; with $298,627,213, or 72.1 per cent, in 1890; and with $131,559,449, or 62.7 per cent, in 1880. The average number of wage-earners employed in 1905 was 176,319, or 72.6 per cent of the total number, compared with 161,183, or 72.4 per cent, in 1900; with 124,704, or 72.8 per cent, in 1890; and with 83,276, or 59.1 per cent, in 1880. The wages paid in 1905 aggregated $106,667,940, or 75.4 per cent of the total amount, compared with $91,279,590, or 75.5 per cent, in 1900; with $68,033,689, or 76.2 per cent, in 1890; and with $35,869,638, or 64.7 per cent, in 1880. The cost of materials in 1905 aggregated $492,538,582, or 79.4 per cent of the total, compared with $416,201,353, or 79.7 per cent, in 1900; with $254,811,212, or 77.9 per cent, in 1890; and with $131,242,090, or 68.6 per cent, in 1880. The value of the products aggregated $711,440,729, or 78.5 per cent of the total in 1905, compared with $633,683,600, or 78.8 per cent, in 1900; with $368,789,503, or 77 per cent, in 1890; and with $201,039,917, or 67.8 per cent, in 1880.

The state of New York ranked fourth in the value of all iron and steel products in 1905, whereas in 1900 it was eighth; Alabama was fifth, instead of sixth as in 1900; New Jersey was sixth, whereas in 1900 it was fourth; West Virginia, seventh (same in 1900); Indiana,

eighth (fifth in 1900); Maryland, ninth (eleventh in 1900); Massachusetts, tenth (ninth in 1900); Wisconsin, eleventh (tenth in 1900); Colorado, twelfth; Michigan, thirteenth (fourteenth in 1900); Kentucky, fourteenth (thirteenth in 1900); and Connecticut, fifteenth. None of the other states exceeded $5,000,000 in value of iron and steel products.

An increase in value of products is shown for all states given in detail except for Delaware, Indiana, New Jersey, and Virginia. Delaware shows a decrease in products of 49.4 per cent, with a decrease in materials used, wage-earners, and wages paid, accompanied by a very considerable increase in capital; Indiana shows a decrease in products of 12.5 per cent, and a decrease in cost of materials, wage-earners, and wages paid, likewise accompanied by an increase in capital; New Jersey shows a decrease of 2.9 per cent in value of products, with a decrease in cost of materials, and an increase in wage-earners, wages paid, and capital; and Virginia shows a decrease of 41.7 per cent in value of products, with a decrease in cost of materials, wage-earners, wages paid, and capital.

COMPARATIVE PRODUCTION BY STATES.

Table 3 shows the production of all forms of iron and steel, by states, from 1870 to 1905, and the rank of each producing state in quantity of products, for each census.

TABLE 3.—IRON AND STEEL—QUANTITY OF CLASSIFIED PRODUCTS, BY STATES, WITH RANK OF STATES: 1870 TO 1905.

STATE.	RANK.					QUANTITY (TONS).				
	1905	1900	1890	1880	1870	1905	1900	1890	1880	1870

[1] Exclusive of 4,184 tons of steel castings made by establishments engaged primarily in the manufacture of other products.

In 1905, 27 states figure as producers, as against 29 in 1900, no products being reported from North Carolina and Wyoming. Production has increased in all states with the exception of Wisconsin, Tennessee, Virginia, Kentucky, Delaware, Minnesota, Texas, and Maine.

Pennsylvania, Ohio, Illinois, and Alabama hold the first four ranking positions, as they did in 1900 and 1890, and produced as a whole 29,131,319 tons, or 83.6 per cent of the total production, compared with 84.2 per cent in 1900, 81 per cent in 1890, 69.2 per cent in 1880, and 63.5 per cent in 1870. Pennsylvania increased its output 14.8 per cent over 1900, and produced 50.4 per cent of the total products in 1905, 51.8 per cent in 1900, 53 per cent in 1890, 49.8 per cent in 1880, and 50.3 per cent in 1870. The product of Ohio shows an increase of 23.1 per cent over 1900, and forms 18.7 per cent of the total in 1905, compared with 18 per cent in 1900, 13.6 per cent in 1890, 12.8 per cent in 1880, and 12.3 per cent in 1870.

The product of Illinois in 1905 increased 12.3 per cent over that of 1900, and constituted 9.5 per cent of

the total, as compared with 10 per cent in 1900, 9.1 per cent in 1890, 5.8 per cent in 1880, and seven-tenths of 1 per cent in 1870. Alabama produced 33.2 per cent more iron and steel products in 1905 than in 1900, and they constituted 5 per cent of the total, as against 4.4 per cent in 1900, 5.3 per cent in 1890, nine-tenths of 1 per cent in 1880, and two-tenths of 1 per cent in 1870.

New York advanced in 1905 to fifth place, and shows an increase of 147.9 per cent over its product of 1900. It produced 3.4 per cent of the total in 1905 and 1.6 per cent in 1900.

West Virginia, although showing a large increase (20.9 per cent) in product over 1900, was outstripped by New York, and moved back to sixth place.

Maryland increased its output 30 per cent over 1900; Indiana, 4.8 per cent; and New Jersey, 45 per cent. Wisconsin shows a loss of 4.2 per cent; Michigan, a gain of 47 per cent; Tennessee, a decrease of 16.7 per cent; Virginia, a decrease of 33.3 per cent—dropping from seventh to thirteenth place; Colorado, an increase of 15.4 per cent; Kentucky, a decrease of 21.1 per cent; Massachusetts, an increase of 4.8 per cent; Connecticut, an increase of 94.9 per cent; and Missouri, an increase of 3.7 per cent. Of the states producing smaller amounts, Georgia shows a relatively large gain of 290.9 per cent, and Rhode Island and Oregon show products approximately fourfold those of 1900.

CAPITAL.

Table 4 presents the capital invested in the active and idle establishments of the iron and steel industry for the census years from 1880 to 1905, inclusive. The capital invested in rented property is included. Plants in course of construction are not included.

TABLE 4.—*Iron and steel—active and idle establishments—capital: 1880 to 1905.*

	Census.	Number of establishments.	CAPITAL.		
			Total.	Buildings, machinery, tools, and implements.	Land, cash, and sundries.
Total	1905	759	[1] $992,774,034	$570,808,117	$421,965,917
	1900	763	[1] 608,898,516	300,365,655	308,532,861
	1890	838	[1] 426,413,902	209,382,875	217,031,027
	1880	992	228,844,953	121,414,777	107,430,176
Active	1905	606	948,689,840	536,999,569	411,690,271
	1900	669	590,530,484	287,669,533	302,860,951
	1890	719	414,044,844	200,197,208	213,847,636
	1880	792	209,904,965	112,320,428	97,584,537
Idle	1905	153	44,084,194	33,808,548	10,275,646
	1900	94	18,368,032	12,696,122	5,671,910
	1890	119	12,369,058	9,185,667	3,183,391
	1880	200	18,939,988	9,094,349	9,845,639

[1] Includes value of rented property—1905, $13,193,239; 1900, $17,245,416; 1890, $8,291,058.

In 1905 the capital invested in idle establishments was 4.4 per cent of the total, as compared with 3 per cent in 1900, 2.9 per cent in 1890, and 8.3 per cent in 1880. Of the number of establishments, 20.2 per cent were idle in 1905, compared with 12.3 per cent in 1900, 14.2 per cent in 1890, and 20.2 per cent in 1880.

The distribution of the invested capital between blast furnace establishments, steel works and rolling mills, and forges and bloomeries for the several census years, with the percentage each is of the total capital, 1880 to 1905, inclusive, is shown in Table 5.

TABLE 5.—IRON AND STEEL—ACTIVE AND IDLE ESTABLISHMENTS—CAPITAL, BY BRANCHES: 1880 TO 1905.

	Census.	TOTAL.		BLAST FURNACES.		STEEL WORKS AND ROLLING MILLS.		FORGES AND BLOOMERIES.		PER CENT OF TOTAL.		
		Number of establishments.	Capital.[1]	Number of establishments.	Capital.	Number of establishments.	Capital.	Number of establishments.	Capital.	Blast furnaces.	Steel works and rolling mills.	Forges and bloomeries.

	1880	200	18,939,988	142	14,394,883	33	4,064,355	25	480,750	76.0	21.5	2.5

[1] Includes value of rented property as follows: Blast furnaces—1905, $4,165,283; 1900, $5,087,881; 1890, $5,061,058. Steel works and rolling mills—1905, $9,018,456; 1900, $11,888,815; 1890, $3,230,000. Forges and bloomeries—1905, $9,500; 1900, $236,000.
[2] Less than one-tenth of 1 per cent.

For comparative purposes the capital invested in 1905 in forges and bloomeries is shown in detail, as well as the capital pertaining to blast furnaces, distinct from that invested in steel works and rolling mills; but in the other tables, except as especially noted, statistics for the few existing forges and bloomeries are embodied in the statistics for steel works and rolling mills. The forges and bloomeries as reported both for 1905 and the former years comprise only establishments which manufacture for sale hammered blooms,

bars, etc., and do not include establishments which have rolling mill equipments and consume in their own works the charcoal blooms or bars made.

In comparing capital for 1880 with that of the later years, it should be remembered that the former includes capital invested by iron and steel establishments in mining and in other operations.

The capital invested in steel works and rolling mills has increased, as a rule, faster than the capital invested in blast furnaces, the increase of capital in blast furnaces showing a slight relative increase from 1900 to 1905 over that for steel works and rolling mills, while the capital invested in forges and bloomeries has rapidly decreased. Thus from 1880 to 1890 the total capital invested in steel works and rolling mills increased 135.9 per cent; in blast furnaces, 35.7 per cent; and in forges and bloomeries it decreased 75.5 per cent. From 1890 to 1900 capital of steel works and rolling mills increased 58.3 per cent; that of blast furnaces, 12.3 per cent; and that of forges and bloomeries decreased 42.4 per cent. From 1900 to 1905 capital of steel works and rolling mills increased 62.3 per cent; that of blast furnaces, 65.7 per cent; and that of forges and bloomeries decreased 58.6 per cent.

The average investment in blast furnaces and in steel works and rolling mills per establishment has increased heavily since 1890, as shown by the following tabular statement:

CENSUS.	Blast furnaces.	Steel works and rolling mills.	Forges and bloomeries.
1905	$990,173	$1,499,223	$36,663
1900	580,046	945,224	44,249
1890	374,184	662,638	33,593

In the fifteen-year period the average amount of capital per establishment for blast furnaces and steel works and rolling mills has more than doubled.

Table 6 is a comparative summary, by states, of the capital invested in active and idle establishments from 1880 to 1905.

TABLE 6.—IRON AND STEEL—ACTIVE AND IDLE ESTABLISHMENTS—CAPITAL, BY STATES: 1880 TO 1905.

[7] Includes establishments distributed as follows: Colorado, 1; District of Columbia, 1; Kansas, 2; Maine, 3; Nebraska, 1; New Hampshire, 2; North Carolina, 20; Oregon, 1; Rhode Island, 3; Utah, 3; Vermont, 4; Wyoming, 1.

MISCELLANEOUS EXPENSES.

In taking the census of 1880 reports of miscellaneous expenses, including expenditures for taxes, rent of offices, interest, insurance, advertising, etc., were not secured. At the census of 1890 they were reported, but the miscellaneous expenses chargeable to the mining of ore and coal, the quarrying of limestone, the making of coke or charcoal, and railroad operations, when these were in conjunction with blast furnace operations, were included as well, so that these expenses do not represent those of the iron and steel industry proper.

At the census of 1900 and the present census efforts were made to secure as nearly as possible the miscellaneous expenses chargeable to the operations of the iron and steel departments. The expense of the sales department and amounts expended as commissions on orders has not been included.

The miscellaneous expenses in 1905 constituted 5.7 per cent of all expense reported, compared with 4.7 per cent in 1900 and 4.1 per cent in 1890.

WAGE-EARNERS.

Table 7 shows the average number of wage-earners employed in the iron and steel industry and its several branches for 1880 and subsequent census years and the percentages of men, women, and children employed.

TABLE 7.—IRON AND STEEL—WAGE-EARNERS (MEN, WOMEN, AND CHILDREN), WITH PER CENT OF TOTAL, BY BRANCHES: 1880 TO 1905.

CLASS.	Census.	AVERAGE NUMBER.				PER CENT OF TOTAL.

[1] Less than one-tenth of 1 per cent.

At the census of 1905 the labor employed by blast furnaces constituted 14.5 per cent of the total; that employed by steel works and rolling mills, 85.5 per cent; and that employed by forges and bloomeries was, in comparison, a negligible quantity. In 1900 blast furnace establishments employed 17.7 per cent of all labor; steel works and rolling mills, 82.2 per cent; and forges and bloomeries, one-tenth of 1 per cent. In 1890 blast furnaces employed 19.5 per cent of the total; steel works and rolling mills, 80.2 per cent; and forges and bloomeries, three-tenths of 1 per cent. In 1880 blast furnace labor was 29.6 per cent of the total; that of steel works and rolling mills, 68.3 per cent; and that of forges and bloomeries, 2.1 per cent. It will be seen that the average number of wage-earners employed in the steel works and rolling mill branch of the industry has constituted in each successive year a larger proportion of the total, increasing from 68.3 per cent in 1880 to 85.5 per cent of all labor in 1905; that the wage-earners employed in the blast furnace branch have fluctuated in number, but constitute a smaller portion of the total, decreasing from 29.6 per cent in 1880 to 14.5 per cent in 1905; and that the labor employed in forges and bloomeries has rapidly decreased.

The women and children employed as wage-earners are practically all in steel works and rolling mills. The women employed are distributed, in the order of numbers, in New Jersey, Pennsylvania, Illinois, Ohio, Massachusetts, New York, Connecticut, Indiana, Maryland, Kentucky, and California. The main increase in number, 1900 to 1905, has been in the states of New Jersey, Illinois, Ohio, Connecticut, and New York. The total number of children employed remained substantially the same, the decreases in certain states counterbalancing the increase in others. The principal increases in number of children employed, 1900 to 1905, have been—in Alabama, from 24 to 181; in Pennsylvania, from 1,082 to 1,236; in Maryland, from 23 to 75; in Ohio, from 43 to 72; in Kentucky, from 15 to 35; and in Delaware, from 9 to 27. New Jersey and New York reported 65 and 18, respectively, in 1900, and none employed in 1905. Illinois shows a decrease from 193 to 13; Indiana, from 80 to 3; West Virginia, from 140 to 84; and Missouri, from 15 to 4.

MATERIALS USED.

The statistics with respect to the materials used in the iron and steel industry—blast furnaces, steel works and rolling mills, and forges and bloomeries—for the census years 1880, 1890, 1900, and 1905 are given in Tables 8, 9, and 10, which follow. In taking the census of 1900, as well as that of 1905, an effort was made to obtain the cost of materials used, f. o. b. cars at point of shipment, in order that the amount paid for freight charges might be definitely ascertained. This proved futile, however, as some establishments reported cost of materials f. o. b. works, while others reported the cost at point of shipment and the total amount paid as freight as a separate item, and still others reported partly one way and partly the other. At the census of 1890, as well as in that of 1880, the cost reported for materials used was the cost at the works. When freight charges for 1905 are not combined in the cost reported, the amount is shown in the detailed tables at the end of this report, as a separate item.

Table 8 shows the quantity and cost of fuel used in blast furnaces, steel works and rolling mills, and forges and bloomeries in 1880, 1890, 1900, and 1905, by kinds. In the case of steel works and rolling mills in 1905, owing to an effort to secure a segregation of fuel used for power from that used for heating and melting purposes, the value of the fuel used for power was reported, but not the kind and quantity of fuel so used.

TABLE 8.—IRON AND STEEL—FUEL CONSUMED, BY KIND, QUANTITY, AND COST, BY BRANCHES: 1880 TO 1905.

[1] Not reported separately.

[2] For steam raising.

The cost of fuel used for power, as reported for steel works and rolling mills, amounted to $12,433,414. As this fuel is not distributed by kinds, either as to quantities or values, no comparisons of 1905 with the former years can properly be made, so far as the fuel consumed by steel works and rolling mills or the total fuel consumption by kinds is concerned. The total cost of the fuel consumed shows an increase of 47.2 per cent for 1905 over 1900, as compared with an increase of 20 per cent for 1900, and 54.5 per cent for 1890. The fuel consumed by blast furnaces shows an increase of 42.2 per cent in 1905, as against 16.7 per cent in 1900, and 72.9 per cent in 1890. The fuel cost for steel works and rolling mills shows an increase of 57.4 per cent in 1905, as against 28.4 per cent in 1900, and 31.8 per cent in 1890. Forges and bloomeries, on the other hand, show a decrease of 80 per cent in 1905, 68.5 per cent in 1900, and 67.1 per cent in 1890.

The fuel consumed in the pig iron industry at different census years is comparable by kinds, and the statistics show that the increase is in coke consumption, the use of bituminous coal and anthracite coal both showing a decrease. Anthracite coal and culm has decreased steadily, at the rate of 23 per cent in 1890, as compared with 1880; 50.7 per cent in 1900, as compared with 1890; and 36.8 per cent in 1905, as compared with 1900. Bituminous coal and slack shows a decrease in 1905, as compared with 1900 and 1880, though the amount consumed in 1890 was materially less, as reported, than in the preceding and later years. The consumption of coke shows a steady and heavy increase, namely, 334.1 per cent in 1890, 78.2 per cent in 1900, and 19.9 per cent in 1905.

The consumption of charcoal shows an increase of 20.3 per cent in 1905 over 1900; a decrease in 1900 of 53.6 per cent over 1890; and an increase of 25.5 per cent in 1890 over 1880. These changes are in keeping with the increase of the charcoal pig iron product from 1880 to 1890, the decrease in 1900, and the increase shown in 1905.

Table 9 shows the quantity and cost of iron ore, mill cinder, and fluxing material consumed in the manufacture of iron and steel in the several census years, 1880 to 1905.

TABLE 9.—IRON AND STEEL—QUANTITY AND COST OF IRON ORE, MILL CINDER, AND FLUXING MATERIAL CONSUMED, BY BRANCHES: 1880 TO 1905.

	Census.	TOTAL.		BLAST FURNACES.		STEEL WORKS AND ROLLING MILLS.		FORGES AND BLOOMERIES.	
		Tons.	Cost.	Tons.	Cost.	Tons.	Cost.	Tons.	Cost.

	1900	1,600,313	3,772,385	1,600,313	3,772,385	.....	.....	.....	.....
	1890	1,145,599	3,086,808	1,145,599	3,086,808	.....	.....	.....	.....
	1880	316,114	910,667	316,114	910,667	.....	.....	.....	.....
Fluxing material	1905	8,327,221	6,892,671	8,327,221	6,892,671	.....	.....	.....	.....
	1900	7,326,706	5,059,632	7,326,706	5,059,632	.....	.....	.....	.....
	1890	5,021,688	4,196,878	5,021,688	4,196,878	.....	.....	.....	.....
	1880	2,829,598	2,547,336	2,829,598	2,547,336	.....	.....	.....	.....

The consumption of iron ore increased 18.9 per cent in 1905 over 1900, as compared with an increase of 65.3 per cent shown in 1900 and an increase of 126 per cent in 1890. The relatively small amount used in steel works and rolling mills, it will be observed, showed a large decrease in 1900, largely due to decrease in the number of active puddling furnaces. The decrease in the amount of iron ore consumed by steel works and rolling mills has been more than regained through the general growth of the industry, the amount consumed in 1905 slightly exceeding that used in 1890. No consumption of iron ore is reported by the forges and bloomeries manufacturing blooms and bars for sale. The iron ore consumed shows an average cost of $3.38 per ton in 1905, as compared with $2.61 in 1900, $4.30 in 1890, and $5.30 in 1880.

The mill cinder, scrap, etc., is that which is purchased by the reporting establishments and does not include such material when made and consumed by the same establishment. The amount shows a steady increase, and an average cost in 1905 of $2.05 per ton, as compared with $2.36 in 1900, $2.69 in 1890, and $2.88 in 1880.

The quantity of fluxing material used shows an increase of 13.7 per cent from 1900 to 1905, 45.9 per cent from 1890 to 1900, and 77.5 per cent from 1880 to 1890. The average cost per ton was 83 cents in 1905, 69 cents in 1900, 84 cents in 1890, and 90 cents in 1880.

Table 10 shows the quantity and cost of pig iron, scrap iron and steel, and all forms of iron and steel purchased and consumed by steel works and rolling mills and forges and bloomeries in 1880, 1890, 1900, and 1905. The scrap iron and steel embraces only purchased material, and does not include scrap produced by iron and steel plants and consumed by the producing establishment.

TABLE 10.—IRON AND STEEL—QUANTITY AND COST OF IRON AND STEEL USED AS MATERIAL: 1880 TO 1905.

KIND.	1905		1900		1890		1880	
	Tons.	Cost.	Tons.	Cost.	Tons.	Cost.	Tons.	Cost.
Total	22,762,901	$366,454,993	18,551,442	$321,146,512	8,735,762	$179,288,771	3,811,289	$113,424,247
Pig iron, spiegeleisen, ferromanganese, and all other pig iron	12,191,228	172,101,436	10,411,281	151,064,348	5,854,252	105,492,718	2,395,333	62,814,151
Old iron or steel rails, and other scrap iron or steel	5,124,277	67,601,248	4,126,980	66,852,621	1,747,591	36,460,815	1,206,818	37,908,350
Purchased hammered iron ore blooms pig or scrap blooms, and imported Swedish billets and bars	81,969	1,781,126	32,720	1,150,575	49,867	2,329,138	92,261	5,993,145
Purchased muck or scrap bar	205,951	5,066,732	161,329	4,535,939	209,534	6,252,594	47,995	2,369,544
Purchased iron or steel ingots, blooms, billets, tin plate bars, sheet bars, or slabs (except imported Swedish billets and bars)	4,632,257	103,420,970	3,682,407	92,123,412	874,518	28,753,506	68,882	4,339,057
Purchased wire rods	161,914	4,774,383	136,725	5,419,617	(1)	(1)	(1)	(1)
Purchased iron or steel skelp	259,643	7,331,935	(1)	(1)	(1)	(1)	(1)	(1)
All other iron or steel	105,662	4,377,163	(1)	(1)	(1)	(1)	(1)	(1)

[1] Not reported separately.

Every kind of iron and steel material purchased shows an increase for the period 1900 to 1905: Pig iron, an increase of 17.1 per cent; scrap iron and steel, 24.2 per cent; hammered scrap blooms and imported Swedish billets and bars, 150.5 per cent; muck or scrap bar, 27.7 per cent; ingots, blooms, billets, etc., not including Swedish billets, etc., 25.8 per cent; and wire rods (purchased), 18.4 per cent. Iron and steel material as a whole increased 22.7 per cent in quantity and 14.1 per cent in value.

PRODUCTION OF IRON AND STEEL.

Table 11 shows the total production of all kinds of iron and steel, by census years, with the percentage of increase or decrease.

TABLE 11.—IRON AND STEEL—QUANTITY OF CLASSIFIED PRODUCTS, WITH PER CENT OF INCREASE, BY BRANCHES: 1880 TO 1905.

	QUANTITY (TONS).				PER CENT OF INCREASE.		
	1905	1900	1890	1880	1900 to 1905	1890 to 1900	1880 to 1890
Total	[1] 34,844,933	29,507,860	16,264,478	6,486,733	18.1	81.4	150.8
Blast furnaces	16,628,294	14,452,234	8,845,185	3,375,912	15.1	63.4	162.0
Steel works and rolling mills	[1] 18,211,013	15,040,129	7,388,244	3,046,038	21.1	103.6	142.6
Forges and bloomeries	5,626	15,497	31,049	64,783	[2] 63.7	[2] 50.1	[2] 52.1

[1] Exclusive of 4,184 tons of steel castings made by establishments engaged primarily in the manufacture of other products. [2] Decrease.

The blast furnace products include spiegeleisen, ferromanganese, ferrosilicon, and castings made direct from the blast furnace. Likewise, there is included in the products of steel works and rolling mills the quantity of steel ingots produced for sale. It should be remembered that duplications are necessarily involved, inasmuch as the blast furnace products enter as material into the output of the steel works and rolling mills, and of the forges and bloomeries, and many steel works and rolling mills produce for sale partially finished products, such as muck and scrap bar, billets, slabs, sheet bars, tin plate bars, etc., which figure as material purchased in the reports of other establishments when they are rolled into finished forms. In many instances there is even a second and a third duplication. However, as similar methods of tabulation were employed in previous censuses, the totals are directly comparable.

NUMBER, EQUIPMENT, AND CAPACITY OF IRON AND STEEL ESTABLISHMENTS.

Table 12 shows the number of blast furnaces, steel works and rolling mills, and forges and bloomeries, both active and idle, in the United States in 1905, compared with 1900, 1890, and 1880, and the equipment and capacity of the same.

TABLE 12.—*Iron and steel—active and idle establishments—number, equipment, and capacity: 1880 to 1905.*

	1905	1900	1890	1880
Blast furnaces:				
Number of establishments	265	273	377	483
Number of completed furnaces	435	399	559	681
Total daily capacity, tons of pig iron	87,498	58,569	37,889	17,186
Steel works and rolling mills:				
Number of establishments	[1] 518	476	429	391
Total daily capacity, finished rolled and forged products, tons, double turn	[1] 115,210	90,122	41,576	19,730

Bessemer steel converters, number	103	91	97	24
Total daily capacity, tons of ingots, double turn	45,427	38,420	19,285	3,988
Open-hearth steel establishments, included above	126	96	58	25
Open-hearth furnaces, number	515	331	129	37
Total daily capacity, tons of ingots, double turn	35,457	19,030	3,608	738
Acid furnaces, number	159	152	.....	.....
Total daily capacity, tons of ingots, double turn	7,750	6,419	.....	.....
Basic furnaces, number	356	179	.....	.....
Total daily capacity, tons of ingots, double turn	27,707	12,611	.....	.....
Crucible steel establishments, included above	49	40	47	37
Number of pots which can be used at a heat	2,939	2,619	2,606	2,601
Forges and bloomeries:				
Number of establishments	7	14	32	118
Total daily capacity, tons of blooms, billets, and bars, double turn	92	143	263	464

[1] Includes 31 establishments other than steel works and rolling mills. (See Table 13.)

Table 12 includes the establishments classified as "other than steel works and rolling mills," which are given in detail in Table 13.

A concentration of the pig iron industry has continued, as shown by the decrease in number of establishments for each successive census, but the completed furnaces in 1905 show an increase of 36 in number, though at each prior census there was a marked decrease, due chiefly to the dismantling of stacks which were badly located and not equipped for competition with the large modern furnaces. The daily capacity of the furnaces, however, has rapidly increased, the increase being 49.4 per cent from 1900 to 1905, as compared with a decade increase of 54.6 per cent for 1900, and 120.5 per cent for 1890; and in average capacity per furnace there is shown a steady increase from 25 tons per day in 1880 to 68 tons in 1890, 147 tons in 1900, and 201 tons in 1905. The pig iron product for 1905 was 52.1 per cent of the yearly capacity (365 days) of all completed furnaces, as compared with 67.6 per cent in 1900, 64 per cent in 1890, and 53.8 per cent in 1880.

The steel works and rolling mills show an increase in number, and in fact the number of plants is in excess of the number of establishments reported; for, as before explained, in some cases the operations of two or more mills, when under one ownership and within the same municipality or district, are covered by one report. The capacity in finished rolled and forged products of all steel works and rolling mills increased 110.7 per cent for the decade ending 1890, 116.8 per cent for 1900, and 27.6 per cent for the five-year period 1900 to 1905. The average daily capacity per establishment in finished rolled and forged products, double turn, increased from 50 tons in 1880 to 97 tons in 1890, 189 tons in 1900, and 222 tons in 1905.

The tonnage of rolled, forged, and other classified products amounted in 1905 to 52.8 per cent of the yearly capacity of all steel works and rolling mills, computed on the basis of 300 working days, double turn, as compared with 55.6 per cent in 1900, 59.2 per cent in 1890, and 51.5 per cent in 1880.

The output of Bessemer steel, ingots and castings, for 1905, in like manner was 57 per cent of the capacity of all converters for the year (300 days), double turn, as compared with 65.3 per cent in 1900, 62.5 per cent in 1890, and 73.5 per cent in 1880. And the open-hearth

steel products, ingots and castings, was 54.7 per cent of the yearly capacity (300 days) of all open-hearth steel furnaces, on double turn, as compared with 53.3 per cent in 1900. The acid open-hearth furnace product in 1905 was 32.5 per cent of the furnace capacity, as compared with 46.2 per cent in 1900; and the basic open-hearth product was 60.9 per cent of the furnace capacity, against 56.9 per cent in 1900. The crucible steel establishments show a substantial increase in number and in pot capacity.

The establishments referred to as "other than steel works and rolling mills," and which have rolling mill facilities or steel making conveniencies, are given in Table 13. The table shows the number of establishments, the character of the products manufactured, and the equipment and daily capacity, by states.

IRON AND STEEL INDUSTRY, BY GEOGRAPHIC DIVISIONS.

Table 14 presents the leading statistics, by geographic divisions for the census years 1880 to 1905, for the industry as a whole and for blast furnaces, and steel works and rolling mills, with forges and bloomeries combined with the latter for comparative purposes.

The New England states include Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut; the Middle states, New York, New Jersey, Pennsylvania, and Delaware; the Southern states, Maryland, Virginia, District of Columbia, West Virginia, North Carolina, Georgia, Alabama, Kentucky, Tennessee, and Texas; and the Western states, Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Iowa, Missouri, Nebraska, Kansas, Colorado, Wyoming, Oregon, Washington, and California. All of these states produced iron and steel during one or more of the years covered by the table. The states of New Hampshire, Vermont, North Carolina, Iowa, Nebraska, and Wyoming, and the District of Columbia, do not appear as producers in 1905.

The forges and bloomeries, combined with steel works and rolling mills in the above table, include establishments distributed at the several censuses as follows: In 1905, 6 establishments, of which 5 were in the Middle states and 1 in the Southern states; in 1900, 7 establishments, of which 6 were in the Middle states and 1 in the Southern states; in 1890, 20 establishments, of which 19 were in the Middle states and 1 in the Southern states; and in 1880, 93 establishments, of which 1 was in New England, 53 in the Middle states, 36 in the Southern states, and 3 in the Western states.

Each of the geographic divisions shows a gain, whether measured by investment of capital, by wage-earners employed, or by tonnage or value of products. A decrease in number of establishments is found in all of the divisions except in New England, where there is an increase of 2.

In connection with Table 14 there is presented Table 15, which shows the per cent of increase of the several items of inquiry for the industry as a whole and the two branches thereof, by geographic divisions, for each census year, 1880 to 1905; also Table 16, which shows the per cent of the total capital and products, value and quantity, by geographic divisions, for each census year.

TABLE 14.—IRON AND STEEL—COMPARATIVE SUMMARY, BY BRANCHES AND GEOGRAPHIC DIVISIONS: 1880 TO 1905.

DIVISION.	Census.	Number of establishments.	Capital.	Salaried officials, clerks, etc.		Wage-earners and wages.		Miscellaneous expenses.	Cost of materials used.	Value of products.	Tons of products.
				Number.	Salaries.	Average number.	Wages.

[1] Includes value of rented property—1905, $12,106,619; 1900, $16,968,821; 1890, $8,273,058.
[2] Exclusive of 4,184 tons of steel castings, valued at $347,264, made by establishments engaged primarily in the manufacture of other products.
[3] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Not reported.

	1900	27.6	26.7	27.9	30.6	30.8	30.5	33.0	31.6	34.2
	1890	24.4	25.2	24.0	27.1	27.2	27.0	27.8	27.1	28.7
	1880	21.3	24.2	19.1	26.5	27.6	26.0	26.8	26.4	27.1

At each census the Middle states or division has ranked first; the Western, second; the Southern, third; and the New England, fourth, with respect to capital, average number of wage-earners, and products, whether measured by value or quantity, in the industry as a whole and in each of the branches; excepting that in 1900 the New England states ranked third in capital invested in steel works, rolling mills, forges and bloomeries, and the Southern, fourth; and in 1890 the Southern ranked second in average number of wage-earners and the Western, third.

In the matter of absolute increase in the principal items for the census period 1900 to 1905, the geographic divisions rank in the same order, the increase in capital ranging from an increase of $234,842,289 in the Middle states, as deduced from Table 14, to an increase of $6,330,185 in the New England states; and in products, from an increase of $50,510,679 in value and 3,078,007 tons in quantity in the Middle states to an increase of $661,940 in value and 78,544 tons in quantity in the New England states.

The rates of increase and the proportions of the totals of capital and products presented in Tables 15 and 16, respectively, have varied, however, very materially. For the period 1880 to 1890 capital increased at the greatest rate in the Western division, with the Southern second in this respect, and the Middle third. In the case of products the Southern division showed the greatest rate of increase, with the Western second and the Middle third. The growth in the Southern division during the period was chiefly in the pig iron industry, and the ratio of increase therein largely exceeded that of the other divisions. In the steel works and rolling mills branch of the industry, including forges and bloomeries, the rates of increase in the Middle and Western divisions were approximately the same and much greater than in the Southern division. During this census period the increase in New England was small and confined to the steel works and rolling mills; blast furnaces showing a decrease for all items except in tonnage of pig iron.

For the census period 1890 to 1900 the proportionate increase in capital was largest in the New England states and all in the steel works and rolling mills section. The Western division was next, and had the largest increase in products in the industry as a whole and in both of its branches, followed by the Middle division and then by the Southern.

For the census period 1900 to 1905, ignoring the New England division, which shows large proportionate increase in tonnage of products though the quantity is small, the Middle division shows the greatest rate of increase both in capital and in tonnage of products, followed by the Western and then by the Southern; while the Western division leads in this respect in value of products. In each case the rate of increase is greatest in the steel works and rolling mills branch of the industry. It will be seen by reference to Table 16 that during the twenty-five years since 1880 the proportionate share of the total capital invested has largely increased for the Western division for both branches of the industry; in the Southern division it has increased for blast furnaces and decreased for steel works and rolling mills and the industry as a whole; and in the Middle division it is practically unchanged for steel works and rolling mills and has

decreased for blast furnaces and the industry as a whole. In the matter of products the proportionate share of the Western division has increased in value and quantity for the industry as a whole and in both departments; the Southern division has increased its proportionate share of blast furnace products and for the industry as a whole, with a decrease in the proportion of the products of steel works and rolling mills; while the Middle division shows a material proportionate decrease in the tonnage and value of products for blast furnaces and the industry as a whole, with a small decrease in the proportionate share of the tons of products of steel works and rolling mills and a slight increase in value. In general, Tables 15 and 16 show for the quarter of a century a more rapid growth in the Western and Southern states, and in the case of the former group a material increase in relative importance.

The following tabular statement shows the percentage of the products both as to value and quantity, contributed by the two branches of the industry, by geographic divisions, for each census from 1880 to 1905:

Per cent of total value and quantity of products, by branches and geographic divisions: 1880 to 1905.

DIVISION.	Census.	VALUE.		TONS.	
		Blast furnaces.	Steel works and rolling mills, and forges and bloomeries.	Blast furnaces.	Steel works and rolling mills, and forges and bloomeries.
United States	1905	25.6	74.4	47.7	52.3
	1900	25.7	74.3	49.0	51.0
	1890	30.4	69.6	54.4	45.6
	1880	30.1	69.9	52.0	48.0
New England states	1905	2.4	97.6	5.8	94.2
	1900	1.8	98.2	6.6	93.4
	1890	5.9	94.1	14.2	85.8
	1880	7.2	92.8	14.5	85.5
Middle states	1905	22.7	77.3	44.8	55.2
	1900	22.9	77.1	45.1	54.9
	1890	28.1	71.9	50.5	49.5
	1880	30.9	69.1	53.4	46.6
Southern states	1905	46.2	53.8	69.5	30.5
	1900	52.7	47.3	75.1	24.9
	1890	56.3	43.7	79.9	20.1
	1880	33.8	66.2	57.0	43.0
Western states	1905	27.3	72.7	46.1	53.9
	1900	25.9	74.1	47.0	53.0
	1890	30.6	69.4	52.9	47.1
	1880	31.4	68.6	51.4	48.6

For the United States as a whole the products of the steel works and rolling mills constitute approximately three-fourths of the total in value and the blast furnace products one-fourth, and there has been in the main an increase in the proportionate share for steel works and rolling mills with each census. The same may also be said of the Middle and Western states. In the Southern states the blast furnace products form nearly one-half of the total in value and more than two-thirds in tonnage. In 1890, as compared with 1880, there was a very heavy increase in the blast furnace industry in the Southern states, as compared with steel works and rolling mills, since which time the products of the steel works and rolling mills have been gaining on the blast furnaces. In the New England states the blast furnace products form but a small part of the combined total.

The New England states.—In the New England states there is shown a substantial increase in capital since 1900, practically all in steel works and rolling mills; likewise, large increases for the decades ending in 1900 and 1890.

The products of the steel works and rolling mills have increased with each census, and the proportionate share of the total for the United States has slightly increased in tonnage since 1900, although slightly decreasing in proportionate value.

The pig iron product is all charcoal pig.

The 17 establishments in the New England states in 1905 engaged in the manufacture of steel or of rolled iron or steel products do not include 3 establishments otherwise classified, and whose products were all consumed in construction of machinery, etc. The capital invested in the active establishments includes $325,000 of rented property in 1905 and $115,000 of rented property in 1890.

Since the census of 1900 the New England states have become steel producers. There are 9 establishments in Massachusetts, Rhode Island, and Connecticut having steel making equipments, including 2 establishments in Massachusetts otherwise classified, 1 as "foundry and machine shop products," and 1 as "electrical machinery," and 1 in Connecticut classified as "cutlery and edge tools;" but not including 1 governmental establishment. The steel equipment of these establishments includes 3 converters of a daily capacity of 208 tons, including 1 Clapp-Griffiths and 2 Tropenas converters (the Government establishment has 1 Tropenas converter) and 20 open-hearth steel furnaces of 1,095 tons daily capacity, of which 10, of 365 tons daily capacity, are acid, and 10, of 730 tons daily capacity, are basic. Of the open-hearth furnaces, 3 acid furnaces, of 45 tons daily capacity, are in the "otherwise classified" industries. The tabulated steel output of the New England states in 1905 was 300 tons of Bessemer steel ingots; 168,928 tons of open-hearth steel ingots, of which 33,774 tons were acid and 135,154 tons were basic; 2,446 tons of open-hearth steel castings; and 4,778 tons of crucible steel. The total product was 176,452 tons of steel, of a value of $3,963,006.

The Middle states.—The Middle states show a decrease of 46 in the number of establishments, with an increase of $234,842,289, or 65.3 per cent, in capital since 1900, the largest in amount and per cent of any of the divisions for this period. The increase is relatively a little the larger in steel works and rolling mills.

The total number of active blast furnace establishments in the Middle states in 1905 was 79, compared

with 95 in 1900, 140 in 1890, and 179 in 1880. The capital invested includes rented property valued at $2,116,480 in 1905, $3,165,181 in 1900, and $2,210,000 in 1890. The reduction in number of wage-earners employed in the blast furnace industry is due to improvements in equipment, chiefly in the use of pig casting machines and in improved charging and ore handling devices. Of the pig product, 32,704 tons were charcoal pig iron and 8,568,470, mineral fuel pig.

In addition to the 227 establishments in the Middle states that produced steel ingots or castings or rolled iron and steel in 1905, there were 10 establishments otherwise classified. The distribution and equipment of the latter are shown in Table 13. The capital invested in active establishments includes $7,741,886 of rented property in 1905, $10,564,736 in 1900, and $978,000 in 1890.

The Southern states.—The Southern states show a decrease of 11 blast furnace establishments and an increase of 10 steel works and rolling mills, making a net decrease of 1. The increase in the number of wage-earners is relatively small, owing to the fact that in the Southern states the blast furnace branch forms a relatively larger part of the iron and steel industry than in the other divisions, and the improvements in blast furnace equipment have materially reduced the number of wage-earners required.

The capital reported for the furnace establishments in the Southern states includes rented property of the value of $251,500 in 1905, $460,500 in 1900, and $783,000 in 1890.

The steel works and rolling mills in the Southern states do not include 1 establishment classified as "shipbuilding, iron and steel," and having a Tropenas converter, the steel product being used in their works. There is included in invested capital for steel works and rolling mills the value of rented property as follows: $714,000 in 1905, $957,313 in 1900, and $500,000 in 1890.

The steel production of the Southern states in 1905 amounted to 841,671 tons, of a value of $15,302,150. This comprised 607,343 tons of Bessemer steel (606,166 tons of ingots and 1,177 castings), 233,152 tons of basic open-hearth steel ingots, 570 tons of basic open-hearth steel castings, 6 tons of crucible steel ingots, and 600 tons of crucible steel castings. The 10 establishments in the Southern states which are equipped for steel making have 10 Bessemer converters of a daily capacity of 4,460 tons and 21 open-hearth steel furnaces of a daily capacity of 1,496 tons. Of the open-hearth furnaces, 20 are basic and 1 acid. The figures do not include the equipment of 1 establishment otherwise classified, nor one 2-gross ton Tropenas steel converter at the Naval Gun Factory, Washington, District of Columbia.

The Western states.—The value of the rented property included in the amount of capital reported for the Western states was $957,753 in 1905, $1,821,091 in 1900, and $3,687,058 in 1890. The value of the rented property was distributed as follows: In blast furnaces, $790,303 in 1905, $1,271,200 in 1900, and $2,068,058 in 1890; and in steel works and rolling mills, $167,450 in 1905, $549,891 in 1900, and $1,619,000 in 1890.

There were also 17 establishments otherwise classified in the Western states in 1905 which were provided with equipments for the making of steel or rolled iron and steel products for their own use. Four of these establishments reported the manufacture of 3,608 tons of steel as partial products. The distribution and classification of these is given in Table 13.

THE ELECTROTHERMIC METALLURGY OF IRON AND STEEL.

In addition to the iron and steel products which have been considered, certain of the ferroalloys—ferrochrome, ferrosilicon, etc.—were produced by the Electric Smelting and Aluminum Company (The Cowles Company) of Lockport, N. Y., and the Willson Aluminum Company with plants at Holcombs Rock, Va., and Glen Ferris, W. Va. These products are used in the steel industry as steel hardening materials. The statistics relating to these products can not be reported separately, and they are therefore consolidated with those of like products of the electric furnace, such as calcium carbide, carborundum, etc., and reported under the group of "substances produced by the aid of electricity," Group VIII of the report on chemicals.

Except in the ferro products above referred to, the electric furnace does not figure in the census of 1905 as a producing agent in the iron and steel industry. It is likely, however, to become an important feature of the iron and steel metallurgy of the future.

The Héroult furnace has been operated at La Praz, France, and at Kortfors, Sweden, since 1900, and over 5,000 tons of steel have been produced. Extensive tests of the manufacture of pig iron in the Héroult furnace were made during the last year at Sault Ste. Marie, Ontario, under the auspices of a commission appointed by the Canadian government. The Kjellin furnace has been operated at Gysingen, near Stockholm, Sweden, since 1901, and several thousand tons of high grade steel have been produced. The Keller furnace has been operated quite extensively at the works of Keller, Leleux & Co., at Livet and at Kerrousse, France. The Stassano furnace has produced steel in the government gun foundry at Turin, Italy.

Since the close of the canvass for the manufacturing census of 1905 there has been considerable activity in the field of electric smelting. The Héroult electric steel refining process, in a 50-ton per day furnace, has been installed at the works of the Holcomb Steel Company, Syracuse, N. Y., and an electric induction steel furnace (Colby) at the works of Henry Disston & Sons, Philadelphia.

The Virginia Electrolytic Company at Holcombs Rock, Va., an offshoot of the Willson Aluminum Company, now makes ferroalloys and metallic silicon, the Willson Aluminum Company at Glen Ferris, Va., making principally ferrochrome. Considerable quantities of the ferroalloys have also been made in the Niagara Research Laboratories, Niagara Falls, N. Y., and an outcome of this work is the formation in 1907 of the Electro Metallurgical Company for making low carbon ferroalloys at Niagara Falls. The Titanium Manufacturing Company is also erecting works at Niagara Falls for making ferrotitanium.

As a result of the experimental work in iron smelting at Sault Ste. Marie, the Noble Electric Steel Company is erecting a Héroult electric furnace plant for reduction of iron ore at Héroult-on-the-Pitt, Shasta county, Cal. At Newmire, Colo., reduction works have been started by the Vanadium Alloys Company for the production of vanadate of iron and ferrovanadium.

The salient features of the several types of electric furnaces which have been used commercially are as follows:

The Héroult electric furnace, as used for the experimental smelting of iron ore at Sault Ste. Marie, Ontario, consists of a short cylindrical stack having a carbon-lined crucible hearth connected with one circuit terminal, and a massive carbon electrode adjustably suspended from above and extending down into the furnace chamber. The carbon electrode used was 16 by 16 inches by 6 feet long and the furnace chamber was approximately 30 inches in diameter.

The Héroult furnace, as used for steel making, is of the tilting open-hearth type. Two massive electrodes, carried by vertically adjustable supports which are attached to the furnace structure, pass through the roof of the furnace. The current passes from one electrode through an air gap to the slag, through this to the underlying molten metal, thence through the latter and back through the slag and the air gap to the other electrode. It thus forms two arc fields between the slag and the respective electrodes. The intensity of the current is controlled by regulating the gap between the electrodes and the slag.

The Kjellin furnace, as operated at Gysingen, Sweden, is of the induction type, using a primary alternating current of 90 amperes and 3,000 volts and developing in the charge, which is in an annular pocket, a current of 3,000 amperes at 7 volts. In its present form the furnace permits of tipping for pouring the charge. The product is an exceptionally pure steel akin to crucible steel.

The Keller furnace for ore smelting is of the resistance type, and consists in general of two or more shafts connected at the bottom by a lateral canal, which widens out midway between the shafts to form a reservoir, or hearth, for the molten metal. Each shaft has a massive carbon electrode extending down from above, and the charge is fed progressively into the shafts around the electrodes. The molten metal is tapped from the reservoir, or hearth, and the slag is tapped from each shaft at a higher level than the reservoir tap. Certain structural features govern the starting of the furnace. The resistance of the charge develops its heat of fusion, and the reduced metal, flowing along the canal, conducts the current from one shaft to the other.

The Stassano furnace is of the arc type, a 3-phase alternating current being distributed to 3 electrodes which pass into the furnace radially and at an angle inclined slightly downward, and nearly meet in the center above the charge, which is not in circuit. The furnace, its hearth being of a crucible form, stands with its vertical axis inclined about 7 degrees from the vertical, and when in operation the whole furnace is rotated to mix the charge and subject all parts thereof to a uniform heat.

Certain results, as given in the report of the Canadian commission on the electric smelting of iron ores, are as follows: Pig iron (gray iron) to the amount of 11,989 pounds was produced from magnetite ore (55.85 Fe), with charcoal as the reducing agent and limestone and sand as flux, at the rate of 9.92 short tons of pig per 1,000 electric horsepower days. The power used was 221.34 electric horsepower (mean amperes, 4,987; mean volts on furnace, 36.03) and the length of the run was sixty-five hours and thirty minutes. It is stated by Doctor Héroult that an output of 12 tons of pig iron per day may be obtained with 1,000 electric horsepower. On a run on roasted pyrrhotite (45.80 Fe), with charcoal and limestone as above, there was produced 7,336 pounds of ferronickel pig at the rate of 7.038 short tons per 1,000 electric horsepower days. The power used was 222.05 electric horsepower (mean amperes, 5,000; mean volts on furnace, 36.05) and the length of the run was fifty-six hours and twenty-nine minutes.

A description of the Héroult electric steel process, as introduced at the works of Richard Lindenberg, Remscheid, Germany, is given in the Iron Age of August 30, 1906. The plant consists of a 2-ton Wellman open-hearth furnace, in which the raw material, principally scrap, is melted down, and the process is so conducted that the steel is overoxidized. The steel is then transferred to the Héroult electric furnace. The quantity charged is about 2 tons, and the steel is purified in the electric furnace by the addition of scale or ore, and thus the elements in the metals, such as silicon, carbon, manganese, and phosphorus, are oxidized; sulphur, however, is not so affected. The slag is cast off by tilting the furnace. Then a neutral slag is formed by additions of lime and sand, under which deoxidation is carried on by means of carbon. The yield is on an average 92.5 per cent in the form of hammered blooms.

45254—MFG 1905—PT 4—08——4

The phosphorus contents of the steel has averaged 0.005 per cent and the sulphur, 0.012 per cent.

Experience has shown that with a 2-ton furnace the cost of steel can be reduced to 120 marks ($30) per ton, and it is estimated that with a 10-ton furnace it can be brought down to 90 marks ($22.50) per ton. With the 2-ton furnace the requirement of electric power is 360 kilowatts per ton of steel, and with a 10-ton furnace only 150 kilowatts will be required.

In a paper by S. E. Ibbotson, of Sheffield, read at the joint meeting of the Iron and Steel Institute and of the American Institute of Mining Engineers, in London, July, 1906, on the operations of the Kjellin electric steel furnace, it was stated that there was produced during the year ending May 31, 1906, at Gysingen, Sweden, 950 tons of tool steel and special steel ingots from a furnace giving 2,240 pounds of steel per tap. The bulk of the steel was made from charges composed of 80 per cent Swedish pig iron and 20 per cent steel scrap, the percentage of carbon being regulated by the addition of briquettes. The average time per charge for white iron and scrap charges was five and one-half hours and the electrical energy consumed was 886 kilowatt hours per ton. When briquettes were added, the average time per charge was seven and one-eighth hours and the electrical energy consumed was 1,128 kilowatt hours per ton.

In the line of special steels there has been produced tungsten steel (including permanent magnet steel), chromium steel, nickel steel, nickel-chromium steel, self-hardening steel, and high-speed tool steel.

A 736-kw, or approximately 1,000 electric horsepower tilting Kjellin furnace for steel manufacture has lately (1907) been completed at the Roechling iron and steel works in Voelklingen, Germany. It has a capacity of 24 tons of steel, 15 tons being poured at the end of the run, the balance remaining in the furnace for the next run. The following extract from a recent publication is of interest in this connection:[1]

> An interesting and quite novel feature of the same plant is a fourth induction furnace now in course of construction. It has a capacity of 150 tons, but is not intended for steel making and refining proper, but will be used as a mixer and reservoir to keep the hot molten metal, which is tapped from the ordinary metallurgical furnaces and which is to be refined in the electric furnace, in molten condition. From this reservoir molten metal is to be run into the electric furnace right after the completion of a run, so as to maintain as much as possible continuity of operation.
>
> In this connection it is interesting to give a summary of electric induction furnaces installed for commercial operation. In this country we have a Colby induction furnace at the Disston Steel Works in Philadelphia. In Europe the following Kjellin induction furnaces have been installed:
>
> Gysingen, Sweden: 150 kw., 955 kg. (2,100 pounds). This is the original Kjellin furnace.
>
> Gurtnellen, Switzerland: International Calcium Co., 320 kw.
>
> Voelklingen, Germany: Roechling Works. Of the following four furnaces the first three are in operation, the fourth in course of construction: First, 50 to 75 kw., capacity 50 to 60 kg. (110 to 130 pounds); second, 110 to 120 kw., capacity 300 kg. (660 pounds); third, 736 kw., pour 15 tons (15,000 kg., or 33,000 pounds); fourth, a 150-ton mixer to keep the metal molten.
>
> Essen, Germany: Krupp Works, 746 kw.
>
> Sheffield, England: Vickers, Sons & Maxim, 200 kg.
>
> Araga, Spain: 200 kw.
>
> There are further in course of construction a 300 to 400 kw. furnace at Guldsmedshyttan, Sweden, and another furnace of the same capacity at Poldihutte.
>
> From the above figures for the furnaces at Gysingen and Voelklingen the following interesting figures on the relation between capacity of furnace and required electric capacity are derived:

Capacity in kg. steel	50 to 60	300	955	15,000
Electric power in kw	50 to 73	110 to 120	150	736
Approximate ratio of kw. to kg	1-1	1-3	1-6	1-20

These figures are very instructive in showing in a general way how the electric power required per unit of output decreases with increasing capacity of the furnace.

From the foregoing it appears that pig iron can not be produced by electric smelting, along the lines heretofore tried, on a commercial scale to compete with blast furnace production, except under conditions of very cheap electric current and high-priced coke. The Canadian commission reported as their conclusion that, with electric energy at $10 per electric horsepower per year and coke at $7 per ton, the cost of production is approximately the same as the cost of producing pig iron in a modern blast furnace. But this is a cost figure for electric energy that has not been reached except under peculiarly favorable conditions. The utilization of the blast furnace gases in large gas engine plants for the generation of electric power will undoubtedly give comparatively cheap power for electrometallurgic work in the iron and steel industry.

For the production of the ferroalloys the electric furnace has decided advantages over the blast furnace, on account of the high temperature readily attainable. For the production of crucible and high-grade steels the work done in electric furnaces indicates that they will be more and more used and that the electric steel product will be an important feature of the industry in coming years.

BLAST FURNACES.

The statistics concerning the production of pig iron, presented herewith, show the industry according to kind of fuel used, and also by grade of product, as well as for the industry as a whole.

The term "pig iron," used in its broadest sense, includes all ferro products of the blast furnaces, whether run into pigs or used in a molten state in Bessemer converters or open-hearth furnaces. As a matter of fact more than one-third of the pig iron produced is used in a molten state. Pig iron is

[1] Electrochemical and Metallurgical Industry, May, 1907, page 173.

classified according to the kind of fuel used; bituminous pig iron being iron made with bituminous fuel—that is, with coke, or coke and bituminous coal mixed; anthracite pig iron being iron made with anthracite coal, alone or mixed with coke; and charcoal pig iron being iron made with charcoal as fuel. Some charcoal and coke pig iron, made with a mixed fuel of charcoal and coke, was reported in 1900, but none was reported in 1905. The statistics are first presented for the entire industry, and then for the two general groups: mineral fuel—including all pig iron made with bituminous coal, coke, or anthracite coal—and charcoal fuel.

The blast furnace product is also classified or graded according to the use for which it is adapted, or the character of the iron, namely, Bessemer, low-phosphorus, malleable Bessemer, basic, foundry, and forge; and also spiegeleisen, ferromanganese, ferrosilicon, etc.

The active blast furnace establishments were in operation on an average 9.12 months in 1905, compared with 10.16 months in 1900, 9.23 months in 1890, and 8 months in 1880.

The production of all kinds of pig iron in the United States for the census year 1905 amounted to 16,628,294 tons, of a reported value of $228,977,535, compared with 14,452,234 tons, valued at $206,579,400, in 1900. The increase in tonnage was 2,176,060 tons, or 15.1 per cent.

Table 17 shows the growth of the blast furnace industry from 1870 to 1905, by census periods.

TABLE 17.—BLAST FURNACES—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1870 TO 1905.

	CENSUS.					PER CENT OF INCREASE.			
	1905 [1]	1900 [1]	1890	1880	1870 [2]	1900 to 1905	1890 to 1900	1880 to 1890	1870 to 1880

[1] Includes 1 penal institution, the statistics for which are not included in the detailed summary.
[2] Includes idle establishments, which were not reported separately in 1870.
[3] Decrease.
[4] Includes value of rented property—1905, $3,158,283; 1900, $4,896,881; 1890, $5,061,058.
[5] Includes proprietors and firm members with their salaries; number only reported in 1900 and 1905, but not included in this table.
[6] Not reported separately.
[7] Not reported.
[8] Includes value of miscellaneous products for which tonnage was not reported.

A decrease in the number of establishments shown at each census will be noted, together with an increase in capital, operating expenses, and products. In 1905, as compared with 1900, there was a decrease of 33 active establishments, with an increase of $91,333,081 in reported capital. Accompanying the increase in production from 1900 to 1905 there is a decrease of 4,180 in the average number of wage-earners employed, there being 35,178 wage-earners reported in 1905, as compared with 39,358 in 1900. In 1890 the pig iron product showed an average for the year of 265 tons per wage-earner; while in 1900, through the use of larger furnaces, improvements in labor saving devices, etc., the pig iron product per wage-earner had risen to 367 tons. This gain in industrial economy continues, the last census showing an average pig iron product for the year of 473 tons per wage-earner, an increase of 28.9 per cent over 1900. As the number of wage-earners reported for 1880, as well as the amount of wages paid, includes a large number of employees engaged in mining and other operations, no comparisons can be made with that year.

The improvements in equipments and methods has resulted in the steady lowering of the labor item in the cost of production, as shown by the following tabular statement:

Relation of capital and specified items of expense to products.

	1905	1900	1890
Capital, per ton of product	$14.41	$10.26	$15.22
Expense, per ton of product	12.66	11.06	15.00
Salaries	0.17	0.16	0.18
Wages	1.14	1.28	1.65
Miscellaneous expenses	0.59	0.52	0.72
Cost of materials used	10.76	9.10	12.45
Value of all products, per ton of pig iron product	13.95	14.31	16.47

Materials cost $47,431,025 more in 1905 than in 1900, and the average cost of materials per ton of product shows an advance of $1.66 per ton of pig iron over that in 1900, although it is $1.69 per ton of product less than it was in 1890. Miscellaneous expenses, in like manner, show an advance of $2,327,905, and an increase of 7 cents per ton of pig iron product over 1900, but a decline of 13 cents per ton from 1890. The labor cost per ton of pig iron was reduced from $1.65 per ton in 1890 to $1.28 in 1900, a decrease of 22.4 per cent, and a further drop to $1.14 per ton in 1905, or 10.9 per cent.

The reduction in the number of wage-earners employed in the blast furnace industry has been chiefly due to the use of pig casting machines in place of sand casting, and to improvements in charging devices and in ore handling machines for stocking and charging.

The value of the products at the census of 1905 exceeded that in 1900 by $25,065,924, although the average value per ton of pig iron shows a decline of 36 cents. As these values of products include some by-products, they are not to be taken for net pig iron values, which will be considered later.

Table 18 is a comparative summary, by states, of the leading statistics of the pig iron industry for the censuses from 1880 to 1905, inclusive.

In 1905 there were blast furnaces in 23 states, but the furnaces in 3 of these states—North Carolina, Oregon, and Washington—were idle. In 1900 there were blast furnaces in 23 states (in the same states as in 1905), those in 2 states—Washington and Oregon—being idle. In 1890, 24 states produced pig iron, and 1 state—Minnesota—had an idle furnace, and in 1880 there were 22 producing states and 2 states and 1 territory—Minnesota, North Carolina, and Utah—in which the furnaces were idle. Pennsylvania is still far in advance of the other states as a producer of pig iron; Ohio, Illinois, and Alabama follow, as at the last census, in the order named. New York, which ranked seventh in 1900, has advanced to fifth place.

All of the states for which individual figures are given in the foregoing table, except Tennessee and Virginia, show an increase in the value of products from 1900 to 1905; and of the states included under "all other states," Colorado, Connecticut, Maryland, and Massachusetts reported increases in pig iron production. No pig iron product was reported from North Carolina at this census.

The decrease in Tennessee amounted to $1,265,166, or 27 per cent, and in Virginia to $3,161,791, or 48.6 per cent of the output of 1900. There were 13 idle blast furnace establishments reported in Virginia for 1905, and 7 in 1900. Of the 3 states for which detailed statistics were given in 1900 but not in 1905—Maryland, Texas, and West Virginia—Maryland and West Virginia report substantial increases and Texas a relatively large decrease. The decrease in the latter state was due to the fact that 2 blast furnaces which were active in 1900 were idle in 1905. The Texas product for 1905 was solely that of a furnace owned and operated by the state.

As before noted, the wage-earners employed in the manufacture of pig iron were less in number in 1905 than in 1900, although they received a larger average wage and turned out a much larger product.

In the early years practically all pig iron was sand cast, requiring a large amount of labor for handling the same. Now, however, more than one-third is delivered in a molten state to the mixers, converters and furnaces of steel plants, and one-fourth is machine cast.

Less than 40 per cent is represented by sand, chill, or direct castings. These changes in practice account in part for the decrease in blast furnace labor. In addition, the improvements in mechanical charging and in conveniences and methods for handling the slag have reduced the number of men required for a furnace crew.

The following states show fewer wage-earners in 1905 than in 1900, with an increase in the value of products: Alabama, Illinois, Ohio, Pennsylvania, and Wisconsin. The state of Illinois is most marked in this particular, the wage-earners and wages paid showing a decrease of 36.5 and 35.8 per cent, respectively, while the value of products show a large increase. As the quantity rather than the value of products manufactured is the best gauge of progress, a tabular statement is presented herewith showing the number of tons of pig iron produced per wage-earner and the average wage per ton of pig iron produced, for 1890, 1900, and 1905.

	Pig iron, tons per wage-earner.			Average wage per ton of pig iron.		
	1905	1900	1890	1905	1900	1890
United States	473	367	265	$1.14	$1.28	$1.65

This shows an increase in the number of tons of pig iron product per wage-earner of 38.5 per cent from 1890 to 1900, and of 28.9 per cent from 1900 to 1905; while the labor cost per ton of pig iron decreased 22.4 per cent from 1890 to 1900 and 10.9 per cent from 1900 to 1905.

The reduction in the labor factor through the improvements in equipment, as might be expected, is balanced by a coordinate increase in the capital invested. The investment in buildings, machinery, tools, and implements in 1905 in active establishments averaged $8.24 per ton of pig iron produced, as compared with $5.48 per ton in 1900, an increase of 50.4 per cent; and in the 5 leading states noted in the above statement this same item shows a corresponding increase.

TABLE 18.—BLAST FURNACES—COMPARATIVE SUMMARY, BY STATES: 1880 TO 1905.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.

[1] Includes value of rented property—1905, $3,158,283; 1900, $4,896,881; 1890, $5,061,058.
[2] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[3] Not reported separately.
[4] Not reported.
[5] Included in "all other states" in 1900 and 1905.
[6] Included in "all other states" in 1905.
[7] Included in "all other states" in 1890 and 1905.
[8] Includes establishments distributed as follows: Colorado, 1; Connecticut, 2; Kentucky, 1; Maryland, 2; Massachusetts, 1; Minnesota, 1; Missouri, 2; Texas, 1; West Virginia, 3.
[9] Includes establishments distributed as follows: Colorado, 1; Connecticut, 1; Kentucky, 2; Massachusetts, 1; Minnesota, 1; Missouri, 2; North Carolina, 2.
[10] Includes establishments distributed as follows: Colorado, 1; Indiana, 2; Maine, 1; Massachusetts, 1; North Carolina, 1; Oregon, 1; Texas, 1; Washington, 1.
[11] Includes establishments distributed as follows: Indiana, 3; Maine, 1; Massachusetts, 2; Oregon, 1; Vermont, 1.

CAPITAL.

Table 19 shows the number of active and idle blast furnace establishments in the United States in 1880, 1890, 1900, and 1905, and the capital invested.

TABLE 19.—*Blast furnaces—active and idle establishments—capital: 1880 to 1905.*

	Census.	Number of establishments.	CAPITAL. Total.	Buildings, machinery, tools, and implements.	Land, cash, and sundries.
Total	1905	265	[1] $262,395,742	$153,591,699	$108,804,043
	1900	273	[1] 158,352,558	86,103,804	72,248,754
	1890	377	[1] 141,067,408	75,931,198	65,136,210
	1880	483	103,926,245	47,545,631	56,380,614
Active	1905	191	239,559,194	136,960,688	102,598,506
	1900	224	148,226,113	79,235,189	68,990,924
	1890	304	134,608,543	71,236,048	63,372,495
	1880	341	89,531,362	41,268,481	48,262,881
Idle	1905	74	22,836,548	16,631,011	6,205,537
	1900	49	10,126,445	6,868,615	3,257,830
	1890	73	6,458,865	4,695,150	1,763,715
	1880	142	14,394,883	6,277,150	8,117,733

[1] Includes value of rented property—1905, $4,165,283; 1900, $5,087,881; 1890, $5,061,058.

The decrease in the number of all establishments in 1905 from that in 1900 was 8, and from that in 1890, 112. At the census of 1905 there were 74 idle establishments, a relatively larger number than at any census since 1880, but the idle plants were, as a rule, minor ones, as shown by the fact that though they constituted 27.9 per cent of all establishments, the capital invested in them formed only 8.7 per cent of the total.

The increase in capital is very large, being $104,043,184 in 1905, or 65.7 per cent, as compared with 1900; whereas for the decade 1890 to 1900 the increase was $17,285,150, or 12.3 per cent, and for the period 1880 to 1890 the increase was $37,141,163, or 35.7 per cent.

MATERIALS USED.

Table 20 shows in detail the quantities and cost of materials consumed by blast furnaces for each census year beginning with 1880. In 1900 and 1905 the cost of the materials as reported separately by items does not in all cases include freight. Freight not included in the cost of materials, as reported by items, is included under "all other materials." In 1880 and 1890 the cost reported for each material was the total cost at the point of consumption.

TABLE 20.—BLAST FURNACES—MATERIALS USED, BY KIND, QUANTITY, AND COST, WITH PER CENT OF INCREASE: 1880 TO 1905.

[1] Domestic and foreign ore were not reported separately in 1880. [2] Decrease. [3] Short tons. [4] Bushels.

One-half of the foreign ore consumed was used by Maryland furnaces, 46 per cent by furnaces in Pennsylvania, and the remainder by Illinois, New Jersey, Virginia, and Kentucky furnaces. Small amounts only were reported for the last 2 states.

In addition to iron ore there was consumed 1,865,385 tons of mill cinder, scrap, scale, etc., not including runner or other scrap produced by the furnaces reporting. There was thus a total of 31,907,570 tons of constituent material, an increase of 4,931,477 tons over the amount reported for 1900, or 18.3 per cent. From this material there was made in 1905, 16,628,294 tons of pig iron, compared with 14,452,234 tons of pig iron made from 26,976,093 tons of like material in 1900; 8,845,185 tons of pig iron, from 16,168,020 tons of material in 1890; and 3,375,912 tons of pig iron, from 6,795,296 tons of all material in 1880. The percentages of pig iron extraction from iron making material were—in 1905, 52.1 per cent; in 1900, 53.6 per cent; in 1890, 54.7 per cent; and in 1880, 49.7 per cent.

In 1890 Mr. John Birkinbine, special agent in charge of the collection of iron ore statistics for the Eleventh Census, estimated the yield of metal in the blast furnace from foreign iron ore, mill cinder, rolling mill scale, zinc residuum, etc., at about 57 per cent, and the same factor was used by Mr. William G. Gray,

expert special agent for the Twelfth Census, in computing the product derived from all material other than domestic iron ore. Following the same line of deduction, the metal yield from foreign iron ore, and mill cinder, scrap, scale, etc., is estimated for 1905 as 1,536,323 tons, and when this is deducted from the total pig iron product, 15,091,971 tons of pig iron remain as the product from domestic iron ores, or an average yield of metal from domestic iron ore of 51.7 per cent, compared with 53.2 per cent for 1900, 54.4 per cent for 1890, and approximately 48.9 per cent for 1880.

As explained in the report of the Twelfth Census on pig iron production, no statistics of the consumption of foreign iron ore by blast furnaces in 1880 being available, the consumption was estimated from the imports.

PRODUCTS.

The production of pig iron according to the kind of fuel used, and the percentage of total production by fuels for each census year since and including 1880 are shown in Table 21. The production of spiegeleisen, ferromanganese, and direct castings is included.

TABLE 21.—BLAST FURNACES—PRODUCTION OF PIG IRON, INCLUDING DIRECT CASTINGS, CLASSIFIED ACCORDING TO KIND OF FUEL USED, WITH PER CENT OF TOTAL: 1880 TO 1905.

	QUANTITY (TONS).				PER CENT OF TOTAL.			
	1905	1900	1890	1880[1]	1905	1900	1890	1880
Total	16,628,294	14,452,234	8,845,185	3,575,912	100.0	100.0	100.0	100.0
Mixed anthracite coal and coke pig iron	1,274,721	1,796,000	1,660,394	638,027	7.7	12.4	19.1	18.9
Coke and bituminous coal pig iron	14,909,029	12,253,818	6,265,865	1,354,958	89.6	84.8	70.8	40.1
Charcoal pig iron	414,171	303,567	593,492	388,677	2.5	2.1	6.7	11.5
Anthracite coal pig iron	30,373	45,857	295,434	994,250	0.2	0.3	3.4	29.5
Mixed charcoal and coke pig iron	.....	52,992	.....	.....	.....	0.4	.....	.....

[1] The 4,229 tons of direct castings shown in the report for blast furnaces, 1880, have been distributed among the several kinds of pig iron; hence the quantities of pig iron do not agree with the data shown in the report for the Tenth Census.

The production of pig iron with mixed anthracite coal and coke for fuel is less than it was in 1900 by 521,279 tons, and the quantity in 1900, though slightly greater in amount than the 1890 product, was proportionately less than that of 1890 and 1880. The great increase continues to be in bituminous fuel pig iron; that is, in pig iron made with coke alone or with mixed coke and bituminous coal, a mixed fuel of coke and bituminous coal being used to some extent in Ohio and Kentucky.

The increase in coke and bituminous coal pig iron, chiefly coke, for the five-year period since the 1900 census was 2,655,211 tons, or 21.7 per cent; and for the decade from 1890 to 1900 it was 5,987,953 tons, or 95.6 per cent.

Charcoal pig iron shows an increase of 110,604 tons, or 36.4 per cent, over 1900, and it constitutes a slightly larger per cent of the entire product than it did in 1900. The larger part of the increase was in Michigan. In 1900 there was a heavy drop in the production of charcoal pig iron.

Pig iron made with anthracite coal continues to show a heavy decline, and the use of such coal in the production of pig iron is gradually being abandoned. No pig iron made with mixed charcoal and coke fuel was reported at this census.

Table 22 shows in detail the quantity and value of the pig iron made in the United States in 1880, 1890, 1900, and 1905, according to the kind of fuel used, the pig iron product including spiegeleisen, ferromanganese, and direct castings.

[1] The 4,229 tons of direct castings shown in the report for blast furnaces, 1880, have been distributed among the several kinds of pig iron; hence the quantities of pig iron do not agree with the data shown in the report for the Tenth Census.
[2] Decrease.

The spiegeleisen product for the census year amounted to 169,630 tons (see Table 24), and the ferromanganese, to 58,018 tons (the latter including a small amount of ferrophosphorus)—a total of 227,648 tons, valued at $6,084,247, or an average of $26.73 per ton. In 1900 the spiegeleisen product was 163,672 tons and the ferromanganese 51,878 tons, giving a total of 215,550 tons, which was valued at $5,871,955, or an average value per ton of $27.24. This shows for the five-year period an increase in the spiegeleisen product of 3.6 per cent, in ferromanganese 11.8 per cent, and in the combined product an increase of 5.6 per cent in quantity and of 3.6 per cent in value. Of the spiegeleisen and ferromanganese product, 44,203 tons, of a value of $881,307, were made with mixed anthracite coal and coke fuel, and 183,445 tons, of a value of $5,202,940, with coke or coke and bituminous fuel. Spiegeleisen was made in Colorado, Illinois, New Jersey, and Pennsylvania, and ferromanganese, in Pennsylvania. The ferrophosphorus product was from Tennessee.

Direct castings were produced by establishments located in Alabama, Georgia, Illinois, New York, Ohio, Pennsylvania, and Tennessee, to the amount of 9,469 tons, valued at $131,700, an average of $13.91 per ton. This is an increase of 32.9 per cent in quantity and 50.2 per cent in value over 1900. Pig iron used for direct castings was all made with coke or coke and bituminous coal for fuel.

Products other than pig iron amounted to $2,911,591. Of this amount, $338,941 was reported under the heading of "amount received for custom work and repairing," and $2,572,650 for miscellaneous products under the general heading "all other products, including castings made in foundries, granulated slag, cement from furnace slag, slag sold for ballast, etc." In 1900 the value of these miscellaneous products was $99,940. The increase was due to a large extent to the utilization of furnace slag in the manufacture of cement.

Table 23 shows the pig iron product by tonnage, value, and average value per ton, for 1880, 1890, 1900, and 1905, and the total number of completed furnaces for all establishments, whether active or idle, for the same years, by states. Direct castings, spiegeleisen, ferromanganese, and ferrosilicon are included, but not the value of miscellaneous products or the amount received for custom work and repairing.

As in 1900, the highest average values per ton for pig iron are reported for Massachusetts and Connecticut, but details can not be given, as there was but 1 establishment producing pig iron in the former state and 2 in the latter. The product of both states was charcoal pig iron. Colorado comes next, followed by Michigan, which latter state has an average value per ton of $17.09. Nine-tenths of the pig iron product of Michigan was charcoal pig iron.

TABLE 23.—*Blast furnaces—quantity and value of all kinds of pig iron, with average value per ton, by states: 1880 to 1905.*

STATE.	Census.	Number of completed furnaces.	Tons.	Value.	Average value per ton.

[1] Included in "all other states" in 1900 and 1905.
[2] Included in "all other states" in 1905.
[3] Included in "all other states" in 1890 and 1905.
[4] Includes states as follows: Colorado, Connecticut, Kentucky, Maryland, Massachusetts, Minnesota, Missouri, Texas, West Virginia.
[5] Includes states as follows: Colorado, Connecticut, Kentucky, Massachusetts, Minnesota, Missouri, North Carolina, West Virginia
[6] Includes states as follows: Colorado, Indiana, Maine, Massachusetts, North Carolina, Oregon, Texas, Washington.
[7] Includes states as follows: Indiana, Maine, Massachusetts, Oregon, Vermont.

In 1900 the highest value reported for pig iron that could be given in detail was for Georgia, $17.96 per ton, and most of the product was made with charcoal fuel; but at this census the average value for that state is $12.15 per ton, and nearly 60 per cent of the product of the state is made with mineral fuel. Alabama and Tennessee show the lowest average value per ton, $11.29, this being a slight advance for Alabama over the average reported in 1900, which was $11.21, and a decline for Tennessee of $1.25 per ton from the average of 1900. Pennsylvania shows an average value of $13.89 per ton, as against $14.98 for 1900; and Ohio, $13.62 per ton, as against $15.75 for 1900.

Illinois shows a large advance in the average value per ton since 1900, but the average for 1900 is so out of balance with the other states that the figures are open to question.

The average value for the country at large was $13.77 in 1905, $14.29 in 1900, $16.46 in 1890, and $26.13 in 1880. The states showing an average value in 1905 below the general average for the United States are New Jersey, West Virginia, Ohio, Minnesota, Georgia, Virginia, Tennessee, and Alabama; and the states ranging above the general average are New York, Missouri, Pennsylvania, Maryland, Texas, Wisconsin, Illinois, Colorado, Kentucky, Michigan, Connecticut, and Massachusetts.

Table 24 shows the production of pig iron by grades and by states for 1900 and 1905. Statistics by grades were not taken prior to 1900. Low-phosphorus pig iron is below 0.04 per cent in phosphorus and Bessemer pig iron contains from 0.04 to 0.10 per cent. In 1900 both grades were included under Bessemer.

Statistics relating to malleable Bessemer pig iron were not reported separately in 1900. At that census the producers of malleable Bessemer in some cases reported it in the Bessemer class, in other cases as foundry, and in other cases in the class of white and mottled and miscellaneous grades.

Malleable Bessemer pig iron as a classified grade first appears in the reports of the American Iron and Steel Association for the calendar year 1900, the amount reported being 173,413 tons. An increase to 256,532 tons was shown in 1901 and to 311,458 tons in 1902. The rate of growth indicates that the production for the calendar year covered by the census of 1900 was something less than 125,000 tons. Malleable Bessemer, so called, is a Bessemer pig iron low in silicon, and is used for casting purposes.

[1] No production in 1905.

[2] Includes 355 tons of silico-spiegel.

[3] Ferrophosphorus.

The percentage which each grade formed of the total in 1900 and 1905 is shown by the following statement:

GRADE.	PER CENT OF TOTAL PIG IRON PRODUCTION.	
	1905	1900
Bessemer	53.5	58.6
Low-phosphorus	1.2	
Malleable Bessemer	1.9	
Basic	15.4	6.5
Foundry	22.1	24.3
Forge	3.6	7.3
White and mottled, and miscellaneous grades	0.6	1.4
Ferrosilicon	0.3	0.2
Spiegeleisen	1.0	1.1
Ferromanganese	0.3	0.4
Direct castings	0.1	0.1

Bessemer and low-phosphorus combined constituted 54.7 per cent of the total pig iron production of 1905, as compared with 58.6 per cent of 1900, when low-phosphorus was reported under Bessemer. The combined product was 9,087,379 tons, an increase of 611,849 tons over 1900, or 7.2 per cent.

Basic pig iron shows the heavy increase of 172.4 per cent. Its proportion of the total pig iron product increased from 6.5 per cent in 1900 to 15.4 per cent in 1905.

Foundry, forge, and the white and mottled and miscellaneous grades form smaller proportions of the total production than in 1900; in quantity, foundry pig iron has increased but 164,500 tons, or 4.7 per cent, while the amount of forge pig iron is 455,660 tons less than in 1900, or a decrease of 43.1 per cent, and the white and mottled and miscellaneous grades show a decrease of 109,239 tons, or 52.4 per cent. Ferrosilicon shows an increase of 46.5 per cent; spiegeleisen, 3.6 per cent; ferromanganese, 11.8 per cent; and direct castings, 32.9 per cent.

Iron for steel making—comprising Bessemer, low-phosphorus, basic, ferrosilicon, spiegeleisen, and ferromanganese—aggregated 11,921,578 tons, an increase of 2,257,149 tons, or 23.4 per cent over the production of like grades in 1900; while iron for use in puddling furnaces, namely, forge, and white and mottled iron, aggregated 701,040 tons, a decrease of 44.6 per cent. In 1900 pig iron for steel making was a little over seven times that made for use in puddling furnaces, and now it is seventeen times in quantity.

Pennsylvania produced one-half of the Bessemer (50.1 per cent); nearly three-fourths of the low-phosphorus (72.5 per cent); nearly three-fourths of the basic (71.5 per cent); over one-fifth of the foundry (21.7 per cent); more than one-half of the forge (52 per cent); over three-fifths of the spiegeleisen (62.7 per cent); all of the ferromanganese; nearly one-third of the direct castings (31.1 per cent); and relatively small amounts of the remaining grades—namely, malleable Bessemer, 3 9 per cent; white and mottled, and miscellaneous grades, 12.2 per cent; and ferrosilicon, 7 per cent.

Ohio, which was second in total products, was second in the production of Bessemer pig iron (23.8 per cent) and first in malleable Bessemer (40.2 per cent) and in direct castings (54.2 per cent). In basic pig iron Ohio, keeping pace with the large general growth of this grade, has increased from 93,700 tons in 1900 to 206,458 in 1905, or 120.3 per cent, but is now exceeded in basic iron product by Alabama as well as Pennsylvania, and hence ranks third. In direct castings Ohio ranks first, with 54.2 per cent, and in ferrosilicon second, with 31.4 per cent. More than one-half of the ferrosilicon product is reported from Kentucky. Illinois, as in 1900, is the third in the production of Bessemer pig (16 per cent) and second in spiegeleisen (26.2 per cent). Alabama did not produce any Bessemer, but is first in foundry iron (27.9 per cent) and second in basic (11.8 per cent) and in forge (19.2 per cent). The increase in basic pig iron in Alabama over its 1900 production, 235.2 per cent, is relatively the largest for any state that produced basic pig iron in 1900. Eleven states produced Bessemer and low-phosphorus pig iron in 1905 and 12 in 1900; Kentucky, New Jersey, and North Carolina reporting Bessemer pig in 1900 but none in 1905, and Michigan and New York reporting Bessemer in 1905 but not in 1900. Basic pig iron was made in 8 states; malleable Bessemer, in 9; foundry pig, in 16; forge pig, in 10; white and mottled and miscellaneous grades, in 10; spiegeleisen, in 4; ferromanganese and ferrophosphorus each, in 1; ferrosilicon, in 3; and direct castings were made in 7 states.

The production of direct castings and spiegeleisen and ferromanganese, by kind of fuel used, is shown in Table 25.

TABLE 25.—BLAST FURNACES—QUANTITY AND VALUE OF DIRECT CASTINGS, AND SPIEGELEISEN AND FERROMANGANESE, CLASSIFIED ACCORDING TO KIND OF FUEL USED: 1905 AND 1900.

	Census.	TOTAL.		DIRECT CASTINGS.		SPIEGELEISEN AND FERROMANGANESE.	
		Tons.	Value.	Tons.	Value.	Tons.	Value.
Total	1905	[1] 237,117	$6,215,947	9,469	$131,700	[1] 227,648	$6,084,247
	1900	222,673	5,959,617	7,123	87,662	215,550	5,871,955

Charcoal	1905	[2]		[2]		[2]	
	1900	10	121	10	121		

[1] Includes 946 tons of ferrophosphorus.

[2] None reported.

The major part of the pig iron product was made by establishments controlling steel works and rolling mills and for consumption therein. Of the 191 active blast furnace establishments, there were 52, or 27.2 per cent, which reported production of pig iron for consumption in steel works and rolling mills, foundries, etc., controlled by the reporting company. The pig iron product of these establishments amounted to 10,909,371 tons, of which 9,926,545 tons (valued at $138,867,586), or 59.7 per cent of the total tonnage produced by all establishments, was for consumption in steel works and rolling mills under the control of the same company.

The following tabular statement shows the distribution of the pig iron tonnage:

Pig iron production, distributed by classes of establishments and by states: 1905.

STATE.	PIG IRON PRODUCTION.							
	Total.		By companies controlling steel works, rolling mills, foundries, etc.				By all other companies.	
	Number of establishments.	Tons.	Number of establishments.	Total tons.	For consumption in establishments controlled by producing company (tons).	For sale (tons).	Number of establishments.	For sale (tons).
Total	191	16,628,294	52	10,909,371	9,926,545	982,826	139	5,718,923
Ohio	33	2,987,787	12	1,944,524	1,751,730	192,794	21	1,043,263
Pennsylvania	65	7,729,279	26	6,326,215	5,573,898	752,317	39	1,403,063
All other states	93	5,911,229	14	2,638,632	2,600,917	37,715	79	3,272,597

The quantity of pig iron consumed by the steel works and rolling mills was 12,191,228 tons. Hence the pig iron consumed by companies operating steel works and rolling mills and producing their own pig iron constituted 81.4 per cent of the total pig iron so consumed and only 2,264,683 tons, or less than one-fifth, of the pig iron consumed by steel works and rolling mills was by companies not operating blast furnaces. The distribution of the pig iron product can be summarized as follows:

	Tons.
Total production	16,628,294
Consumption by steel works and rolling mills	12,191,228
Production for consumption in establishments controlled by producing company	9,926,545
Purchased from independent establishments	2,264,683
Balance available for foundries, other industries, etc.	4,437,066

Along with the development of the Bessemer and open-hearth steel processes there has resulted the practice of retaining the blast furnace metal in molten condition. For some years it has been the practice to pour the molten blast metal for use in steel manufacture into a large vessel known as a mixer or receiver. By thus mixing the tappings from several blast furnaces, the high silicon or sulphur, for example, in the metal from one furnace is compensated for by low silicon or sulphur in the iron from another, and, along with a certain amount of purification due to chemical action, produces a metal of uniform composition. Mixers capable of holding 600 tons or more of metal are now in use. They are properly, however, an adjunct of the steel plant and not of the blast furnace. The charges of metal are generally transported in large truck ladles from the blast furnace to the mixer, and often for considerable distances, without any material loss of heat.

Casting machines have also been extensively introduced and to a small extent the practice of chill casting or casting on an iron floor.

The following tabular statement shows the quantities of metal handled by the several methods, by states:

Quantity of metal, classified according to method of handling, by states: 1905.

	UNITED STATES.			OHIO.		PENNSYLVANIA.		ALL OTHER STATES.

EQUIPMENT AND PRODUCTION.

Table 26 shows, by states, ranked according to production at the census of 1905, the total number of active and idle furnaces for 1880, 1890, 1900, and 1905, with the production and the per cent of the total production.

TABLE 26.—BLAST FURNACES—NUMBER OF ACTIVE AND IDLE FURNACES AND PRODUCTION OF PIG IRON, WITH PER CENT OF TOTAL, BY STATES, RANKED ACCORDING TO QUANTITY OF PRODUCT: 1880 TO 1905.

STATE.	Census.	Completed furnaces.	PRODUCTION OF PIG IRON. Tons.	Per cent of total.	Rank.

[1] Includes castings made direct from furnace, as follows: 1905, 9,469 tons; 1900, 7,123 tons; 1890, 5,417 tons; 1880, 3,776 tons.

[2] Less than one-tenth of 1 per cent.

During the twenty-five years covered by the statistics the production increased from 3,375,912 tons to 16,628,294 tons, while the number of furnaces decreased from 681 to 435 during the period, a loss of 246, or 36.1 per cent. This condition is the result of an increase in the capacity of the stacks, for in 1880 the average daily capacity per stack was 25 tons; in 1890, 68 tons; in 1900, 147 tons; and in 1905, 201 tons.

There has been an increase of 36 stacks since 1900—12 in Ohio; 9 in Pennsylvania; 4 each in Alabama and Illinois; 3 each in Colorado, New York, and Tennessee; 2 each in Kentucky and New Jersey; and 1 in West Virginia. A decrease is shown in Michigan and Connecticut of 2 each, and in Georgia, Maryland, and Massachusetts of 1 each.

The 4 states of Pennsylvania, Ohio, Illinois, and Alabama produced, all told, 13,849,053 tons, or 83.3 per cent of all pig iron in 1905; 83.1 per cent of the total pig iron production in 1900; 79.5 per cent in 1890; and 69.7 per cent in 1880. Of the remaining states, New York has nearly doubled its production, and Michigan, West Virginia, New Jersey, and Georgia show relatively large gains. Pennsylvania, Ohio, Illinois, and Alabama retain the same rank as in 1900. New York has advanced from seventh place to fifth, Tennessee remains sixth, and Maryland advances to seventh, while Virginia recedes from fifth to eighth.

The furnaces in North Carolina, Oregon, and Washington—2 in the former state and 1 in each of the other states—were idle in 1905. North Carolina, however, was a producer in 1900. The furnaces in Indiana, Maine, Vermont, and Utah were long since abandoned and dismantled.

Table 27 shows the number of active and idle furnaces, by states, for the census years 1900 and 1905.

Since 1900 an increase of 43 stacks appears in certain states and a decrease of 7 stacks in other states. Of the total number of furnaces, more than one-fourth were idle. The largest number of idle stacks in any one state was in Pennsylvania—37—nearly one-fourth of the total number in the state. In Virginia more than one-half of the stacks were idle; in Alabama, nearly one-third; in Ohio, one-fifth; and in Tennessee, nearly one-third. The capacity, however, of the idle stacks is a much smaller part of the blast furnace capacity of the country than their relative numbers would indicate. The 344 furnaces owned by the active establishments, comprising 318 furnaces which were active sometime during the year, and 26 which were idle throughout the year, have a total daily capacity of 78,230 tons, or an average daily capacity of 227 tons per stack; while the 91 furnaces of the establishments idle throughout the year have an aggregate daily capacity of 9,268 tons, or an average of 102 tons per stack. Of the furnaces of idle establishments, 18 were charcoal furnaces, with an aggregate daily capacity of 666 tons, or an average of 37 tons. The idle furnaces of the active establishments are as a rule the smaller furnaces, and below the average in capacity. If, however, the 26 idle furnaces owned by active establishments are given the average capacity of all furnaces owned by the active establishments—227 tons—and their capacity as thus estimated is added to that of the

idle establishments, we obtain a little over 15,000 tons as the total daily capacity of all idle furnaces, or between one-sixth and one-fifth of the total furnace capacity.

Table 28 shows, according to the kind of fuel used, the total number of blast furnaces in the United States for the census years 1880, 1890, 1900, and 1905, whether active or idle, and their daily capacity in gross tons, by states.

	1880	14	422			3	165	11	257

[1] Includes 5 mixed charcoal and coke furnaces of a daily capacity of 350 tons.

For the first time since 1880 there appears an increase in the total number of blast furnaces, the number having increased from 399 to 435 since 1900. With each former census the decrease in number of stacks was large, accompanied by an increase both in aggregate capacity and in average capacity per stack. But during the period from 1900 to 1905 the number of stacks increased 9 per cent, the aggregate capacity 49.4 per cent, and the average capacity 36.7 per cent. The gain was in coke furnaces. Charcoal furnaces decreased in number, with a slight increase in the average daily capacity; and the anthracite and mixed anthracite and coke furnaces decreased considerably both in number and in aggregate capacity. In 1900, 5 furnaces in Tennessee, of a daily capacity of 350 tons, were operated with mixed charcoal and coke fuel. No furnaces operated with mixed charcoal and coke fuel were reported in 1905.

45254—MFG 1905—PT 4—08——5

The growth in the size of furnaces is shown by the following presentation of the average daily capacity of furnaces for the different fuels and for the different census years:

	AVERAGE DAILY CAPACITY IN TONS.			
	1905	1900	1890	1880
All furnaces	201	147	68	25
Coke and bituminous coal furnaces	249	194	101	38
Anthracite and mixed anthracite and coke furnaces	118	100	55	29
Charcoal furnaces	46	41	24	12

The changes going on in furnace equipment—that is, the decrease in the number of anthracite and charcoal furnaces and the increase of the coke furnaces—is readily seen by reference to the table. New York alone shows an increase in charcoal furnaces. New

Jersey, New York, and Pennsylvania, the only states having anthracite and mixed anthracite and coke furnaces in 1900, all show reduced numbers in 1905.

Pennsylvania shows an increase of 25 bituminous (coke) furnaces since 1900, with an increase in average daily capacity per stack from 245 tons in 1900 to 322 tons in 1905. Ohio has an increase of 12 stacks, with an increase in average daily capacity from 220 tons in 1900 to 282 tons in 1905. New York shows an increase of 6 stacks, and an increase in average daily capacity of from 212 tons in 1900 to 292 tons in 1905. Alabama shows an increase of 6 stacks, with an increase in average daily capacity from 155 tons in 1900 to 171 tons in 1905. Illinois has gained 4 stacks, and increased the average daily capacity of its furnaces from 259 tons in 1900 to 322 tons in 1905. Similar gains are shown for Colorado, New Jersey, Kentucky, Michigan, Virginia, and West Virginia; the state of Michigan for the first time reporting a bituminous fuel furnace.

There are reported 31 furnaces of a daily capacity rating of 500 tons or more, distributed as follows: Pennsylvania 21, with an aggregate daily capacity of 11,700 tons; Ohio 7, with an aggregate daily capacity of 3,500 tons; Illinois 2, of 500 tons each; and New York 1, of 600 tons. The largest furnaces are Stacks J and K of the Edgar Thomson group of the Carnegie Steel Company, each of 650 tons rating.

In the presentation of statistics for the census of 1900 mention was made of the production of 901 gross tons of pig iron in a single day in June, 1902, by Furnace E of the Edgar Thomson group of the Carnegie Steel Company, at Bessemer, Pa. This output was exceeded by the same furnace on March 30, 1905, when it produced 918 gross tons of Bessemer pig iron. This is, up to the present time, the world's record for the largest output by a single furnace in twenty-four hours.

At the time of taking the present census the world's record for the longest run was held by Furnace H of the Edgar Thomson group, which was blown in on March 13, 1894, and blown out on June 20, 1903, a run of 3,386 days, during which period it was banked once for thirty-five days. The output of the furnace for the run was 1,256,193 gross tons of pig iron, an average of 374.9 tons per day for the 3,351 days of operating time. The record has since been surpassed by Shoenberger Furnace No. 2, Pittsburg, Pa., of the American Steel and Wire Company, which was blown out on August 1, 1906, after having been in blast for 3,427 days. During this time it was banked twelve times for an aggregate of sixty-six days.

The record for the largest output on a single lining is held by the Duquesne Furnace No. 1 of the Carnegie Steel Company, which produced 1,287,381 gross tons on an unbroken run of 2,024 days—an average of 636.1 tons per day.

Slag pits.—The schedule for the present census contained, for the first time, inquiries in regard to the number of granulated slag pits in use, their capacity, and the purposes for which the granulated slag is used; also the extent of manufacture of cement from slag by blast furnace establishments.

The use of granulated slag pits was reported by 31 establishments, distributed as follows: Pennsylvania, 15; Ohio, 14; Illinois, 1; and New York, 1. These establishments had in the aggregate 47 slag pits, with an annual capacity of 3,338,200 tons. Four of the establishments, located, 1 in Illinois, 2 in Ohio, and 1 in Pennsylvania, reported the use of slag for cement manufacture by the producing company, the cement plants having an annual capacity in excess of 5,000,000 barrels. In addition, 2 establishments reported the sale of slag to cement works. The bulk of the granulated slag is used for filling and railroad ballast.

PIG IRON EXPORTED.

In collecting the statistics for the census of 1900 an inquiry was made as to the amount of pig iron exported by blast furnace establishments, but this inquiry was omitted in taking the census of 1905. The total quantity reported as exported direct by blast furnace establishments in 1900 was 166,625 tons, which was less than 1.2 per cent of the total production. The total amount of pig iron exported in 1901, according to the reports of the Secretary of the Treasury, was 255,253 tons; in 1902 it had declined to 54,704 tons; it was still less in 1903 and 1904; and in 1905 it was only 56,971 tons, or less than three-tenths of 1 per cent of the total production.

POWER.

The blast furnace establishments in operation in 1904 reported in power equipment 1,555 steam engines, with an aggregate of 762,382 horsepower; 27 gas and gasoline engines, having 3,757 horsepower; 21 water wheels, of 680 horsepower; 1,370 electric motors, of 52,471 horsepower; miscellaneous power appliances, of 6,320 horsepower; and 139 electric horsepower rented. These aggregate 825,749 horsepower, as compared with 505,965 horsepower reported at the census of 1900, an increase of 63.2 per cent. In addition, 1 penal institution in Texas reported 5 steam engines with 550 horsepower.

The use of waterpower was reported by 2 active establishments in Connecticut, 1 in Georgia, 2 in Michigan, and 4 in Pennsylvania, and by 1 idle establishment in North Carolina and 1 in Virginia. With the exception of 2 active establishments in Pennsylvania and 1 idle in Virginia, all those which reported waterpower have steampower equipment also.

The idle blast furnace establishments reported 250 steam engines of 89,465 horsepower, 2 water wheels

of 82 horsepower, and 2 electric motors of 78 horsepower—a total of 89,625 horsepower.

The 1,372 electric motors of 52,549 horsepower capacity owned by the active and idle establishments represent secondary power, as they are run by current generated by the establishments reporting. The primary power of all establishments is therefore 863,375 horsepower. This shows an average power equipment of 1,985 horsepower per stack, and of 9.9 horsepower per ton of stack capacity.

In 1900 the corresponding average power equipment per stack was 1,312 horsepower, and per ton of stack capacity it was 8.9 horsepower.

The size of steam engines used (active establishments) has increased from an average of 381 horsepower in 1900 to 489 horsepower in 1905.

THE MANUFACTURE OF PIG IRON WITH MINERAL FUEL.

In 1880 nearly one-half of the pig iron product was made with anthracite fuel—either anthracite alone or anthracite coal and coke mixed. During the following decade bituminous coal and coke forged ahead and outstripped anthracite fuel, and at the present time pig iron made with bituminous fuel constitutes nearly nine-tenths of the total production.

In 1905 the production of anthracite pig iron was but 30,373 tons, and that of pig iron made with mixed anthracite coal and coke had declined from 1,796,000 tons in 1900 to 1,274,721 tons in 1905, a decrease of 29 per cent.

The increase in coke and bituminous coal pig iron, which was very heavy from 1890 to 1900, has continued, and during the period 1900 to 1905 the increase amounted to 2,655,211 tons, or 21.7 per cent. Bituminous pig iron exceeded anthracite in 1905 by 13,603,935 tons.

Table 29 shows the leading statistics of the manufacture of pig iron with mineral fuel for the census years of 1880, 1890, 1900, and 1905.

TABLE 29.—BLAST FURNACES, MINERAL FUEL—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1880 TO 1905.

	CENSUS.				PER CENT OF INCREASE.		
	1905	1900	1890	1880	1900 to 1905	1890 to 1900	1880 to 1890
Number of establishments	160	188	221	225	[1] 14.9	[1] 14.9	[1] 1.8
Capital	[2] $228,895,148	[2] $140,703,112	[2] $116,982,231	$70,262,615	62.7	20.3	66.5

Wages	$17,954,249	$17,830,986	$13,406,085	(4)	0.7	33.0	.....
Women 16 years and over	4	6	.....	(4)	[1] 33.3	.....	.....
Wages	$954	$1,352	.....	(4)	[1] 29.4	.....	.....
Children under 16 years	70	81	65	(4)	[1] 13.6	24.6	.....
Wages	$15,676	$17,432	$12,365	(4)	[1] 10.1	41.0	.....
Miscellaneous expenses	$9,396,115	$7,181,322	$5,330,720	(5)	30.8	34.7	.....
Cost of materials used	$173,885,724	$127,706,216	$101,719,465	$51,254,711	36.2	25.5	98.5
Value of products	$224,433,959	$200,676,934	$133,685,378	$76,739,573	11.8	50.1	74.2
Tons of pig iron	16,214,123	14,095,675	8,251,093	2,987,235	15.0	70.8	176.2

[1] Decrease.
[2] Includes value of rented property—1905, $2,528,600; 1900, $4,623,081; 1890, $4,807,470.
[3] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Not reported.

The number of establishments shows a decrease for each census year, while the capital investment and production shows a constant increase; though, as before explained, through the more general installation of labor saving equipments, the increased production is secured with a considerably less number of wage-earners. The number of active establishments has decreased 28 in number from 1900 to 1905, while the capital invested has increased $88,192,036, or 62.7 per cent. The decrease in number of wage-earners was 4,552, or 12.2 per cent.

In 1890 the yearly pig iron product per wage-earner was 274 tons; in 1900, 377 tons; and at the census of 1905 this average shows a further increase to 493 tons.

The following tabular statement shows, per ton of pig iron produced with mineral fuel, the capital investment, cost of production as shown by the items reported, and value of all products, for 1890, 1900, and 1905:

	1905	1900	1890
Capital	$14.12	$9.98	$14.18
Expenses	12.58	10.99	14.75
Salaries	0.16	0.15	0.15
Wages paid	1.11	1.27	1.63
Miscellaneous expenses	0.58	0.51	0.64
Cost of materials used	10.73	9.06	12.33
Products, value per ton	13.84	14.24	16.20

It will be observed that executive and superintendence expense, as represented by salaries paid and miscellaneous expense, varies comparatively little per ton of product, while the labor item decreases with each

census. The fluctuations in the cost of production are due chiefly to fluctuations in the cost of materials.

In 1890 and 1900 the labor cost of producing a ton of mineral fuel pig iron, as represented by the amount of wages paid at the blast furnaces, was between 11 and 12 per cent of the cost represented by the above items, while in 1905 it was a trifle less than 9 per cent.

Table 30 is a comparative summary, by states, of the leading statistics of establishments manufacturing pig iron with mineral fuel, for 1880, 1890, 1900, and 1905.

TABLE 30.—BLAST FURNACES, MINERAL FUEL—COMPARATIVE SUMMARY, BY STATES: 1880 TO 1905.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.

[1] Includes value of rented property—1905, $2,528,600; 1900, $4,623,081; 1890, $4,807,470.
[2] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[3] Not reported separately.
[4] Not reported.
[5] Included in "all other states" in 1905.
[6] Included in "all other states" in 1900 and 1905.
[7] Includes establishments distributed as follows: Alabama, 17; Colorado, 1; Georgia 1; Kentucky, 1; Maryland, 1; Michigan, 1; Minnesota, 1; Missouri, 1; Ohio, 31; Tennessee, 12; Virginia, 9; West Virginia, 3; Wisconsin, 3.
[8] Includes establishments distributed as follows: Colorado, 1; Georgia, 1; Kentucky, 2; Maryland, 2; Minnesota, 1; Missouri, 1; North Carolina, 2.
[9] Includes establishments distributed as follows: Colorado, 1; Georgia, 2; Indiana, 2; Kentucky, 2; Maryland, 2.
[10] Includes establishments distributed as follows: Georgia, 2; Indiana, 2; Kentucky, 3; Maryland, 4; Massachusetts, 1.

The necessity of including in the group of "all other states" such states as have establishments owned by less than three organizations in either the mineral-fuel branch or the charcoal-fuel branch of the blast furnace industry, in order that the operations of individual organizations may not be disclosed by comparison of the different tables, requires the inclusion under "all other states" of a number of the leading states; notably Ohio and Alabama, which are the second and fourth ranking states, respectively, in the mineral fuel industry, as well as West Virginia, Tennessee, Virginia, and Wisconsin, which rank sixth, eighth, ninth, and tenth, respectively.

Pig iron was produced with mineral fuel in 17 states in 1905. The number is the same as in 1900, Michigan, which did not produce mineral fuel pig iron in 1900,

appearing as a producer in 1905 and replacing North Carolina, whose furnaces, active in 1900, were idle in 1905. There were 16 states that produced mineral fuel pig iron in 1890 and 1880. All of the states for which product value is given in detail show an increase. The largest relative increase in value of product for the period 1900 to 1905 appears in Illinois and the next in New York; the per cent of increase was 80.4 in the former state and 67.8 in the latter. Next in order comes New Jersey, with an increase in value of products of 41.4 per cent, followed by Alabama, which showed a large increase.

It should be noted, however, that the statistics of Illinois for 1900 show an average value per ton of pig iron made with mineral fuel of $10.23 (see Table 34), which is $3.99 per ton less than the average value for the United States, and $4.74 per ton less than the average for Pennsylvania. It is probable that the low average value per ton for pig iron in Illinois in 1900 was due to a misunderstanding of the scope of the census inquiry and to errors in reporting values. If we estimate the value of the Illinois pig iron product for 1900 on the basis of the average value for the United States, $14.22 per ton, we have $20,896,717, instead of $15,033,696, as the value of the pig iron product made with mineral fuel.

The decrease in the number of wage-earners in the blast furnace industry in general has heretofore been noted.

The total value of all products reported by blast furnace establishments in 1905 was $231,889,126, of which amount the mineral fuel furnaces contributed $224,433,959, or 96.8 per cent, compared with 97 per cent in 1900, 91.8 per cent in 1890, and 85.9 per cent in 1880. The state of Pennsylvania produced nearly one-half of the mineral fuel pig iron, and over five-sixths of the entire product was from Pennsylvania, Ohio, Illinois, and Alabama.

Capital.—Table 31 shows the capital invested in blast furnace establishments equipped for the manufacture of mineral fuel pig iron, whether active or idle, for the census years 1880, 1890, 1900, and 1905.

TABLE 31.—*Blast furnaces, mineral fuel—active and idle establishments—capital: 1880 to 1905.*

	Census.	Number of establishments.	CAPITAL. Total.	Buildings, machinery, tools, and implements.	Land, cash, and sundries.
Total	1905	216	[1] $249,101,969	$148,287,198	$100,814,771
	1900	207	[1] 146,556,052	80,989,287	65,566,765
	1890	261	[1] 121,393,241	67,102,965	54,290,276
	1880	271	76,096,698	40,503,972	35,591,726
Active	1905	160	228,895,148	133,280,465	95,614,683
	1900	188	140,703,112	76,415,732	64,287,380
	1890	221	116,962,231	63,798,965	53,183,266
	1880	225	70,262,615	36,605,322	33,657,293
Idle	1905	56	20,206,821	15,006,733	5,200,088
	1900	19	5,852,940	4,573,555	1,279,385
	1890	40	4,411,010	3,304,000	1,107,010
	1880	46	5,833,083	3,898,650	1,934,433

[1] Includes value of rented property—1905, $3,359,600; 1900, $4,763,381; 1890, $4,807,470.

The total capital invested in the mineral fuel branch of the blast furnace industry constitutes 94.9 per cent of the capital in the entire industry, as compared with 92.6 per cent in 1900. In 1890 the percentage was 86.1.

Materials used.—Table 32 shows in detail the quantity and cost of the materials used by the mineral fuel blast furnaces in the manufacture of pig iron in 1880, 1890, 1900, and 1905.

TABLE 32.—BLAST FURNACES, MINERAL FUEL—MATERIALS USED, BY KIND, QUANTITY, AND COST: 1880 TO 1905.

KIND.	1905		1900		1890		1880	
	Tons.	Cost.	Tons.	Cost.	Tons.	Cost.	Tons.	Cost.
Total		$173,885,724		$127,706,216		$101,719,465		$51,254,711
Domestic iron ore	28,393,506	94,173,650	23,916,749	60,595,698	12,886,878	54,006,644	5,642,529	29,689,649
Foreign iron ore	829,918	4,739,123	754,383	4,107,449	965,741	5,860,349	[1]	[1]
Fluxing material	8,256,325	6,821,558	7,223,136	4,980,465	4,885,153	4,038,709	2,727,216	2,446,767
Anthracite coal and culm	560,637	1,812,779	886,564	2,297,419	1,796,854	5,165,761	2,334,984	8,012,755
Bituminous coal and slack	796,113	1,323,646	831,429	1,099,810	491,971	759,522	939,065	2,095,887
Coke	[2] 19,739,671	57,126,997	[2] 16,396,455	38,774,819	[2] 9,237,935	27,435,780	[2] 2,128,255	8,129,240
Mill cinder, scrap, etc.	1,864,836	3,828,916	1,599,364	3,769,161	1,144,974	3,084,391	302,136	841,451
All other materials		4,059,055		12,081,395		1,368,309		38,962

[1] Domestic and foreign ore were not reported separately in 1880.

[2] Short tons.

The consumption of domestic iron ore shows an increase of 4,476,757 tons, or 18.7 per cent; foreign iron ore, an increase of 75,535 tons, or 10 per cent; and mill cinder and scrap reported as purchased—that is, not including runner or other scrap produced by the furnace reporting—an increase of 265,472 tons, or 16.6 per cent. The iron constituent materials in the aggregate amounted to 31,088,260 tons, an increase of 4,817,764 tons over 1900, or 18.3 per cent.

The increase in fluxing material was 1,033,189 tons, or 14.3 per cent. The consumption of anthracite coal and culm fell off 325,927 tons from 1900, or 36.8 per

cent, and the consumption of bituminous coal and slack shows a slight decrease, while coke presents an increase of 3,343,216 short tons, or 20.4 per cent.

The fuels in the aggregate show an increase of 2,623,771 long tons, or 16 per cent, while the increase in the pig iron tonnage was 15 per cent.

The average consumption of constituent materials (ore, mill cinder, and scrap, not including runner or other scrap produced by the furnace reporting), flux, and fuel in producing a ton of mineral fuel pig iron is shown in the following tabular statement, for 1880, 1890, 1900, and 1905:

Materials consumed per ton of pig iron—mineral fuel.

MATERIAL.	POUNDS.			
	1905	1900	1890	1880
Total	7,800	7,666	7,946	10,156
Ore	4,037	3,921	3,760	4,231
Limestone	1,141	1,147	1,326	2,045
Fuel	2,622	2,598	2,860	3,880
Mill cinder, scrap, etc., purchased, not included in total	258	254	312	227

In the fuel consumption given above the amount used for steam purposes is necessarily included, but the amount so used is not relatively large. Excluding mill cinder and scrap, which, as it was only reported where purchased, does not represent all of that class of material used, the per cent that each class of material is of the total for each census year is as follows:

MATERIAL.	PER CENT OF TOTAL.			
	1905	1900	1890	1880
Total	100.0	100.0	100.0	100.0
Ore	51.8	51.1	47.3	41.7
Limestone	14.6	15.0	16.7	20.1
Fuel	33.6	33.9	36.0	38.2

In comparison with the above the following tabular statement is given, showing the average consumption of ore, flux, and coke per ton of pig iron, by certain large furnaces of a daily capacity of approximately 500 tons or more, in Ohio and Pennsylvania. These furnaces produced over 5,000,000 tons of pig iron in 1905.

MATERIAL.	Pounds.	Per cent of total.
Total	7,087	100.0
Ore	3,874	54.7
Limestone	986	13.9
Coke	2,227	31.4

Products.—Table 33 shows the pig iron product of mineral fuel furnaces for 1880, 1890, 1900, and 1905, classified according to the fuel used. The production of spiegeleisen and ferromanganese and direct castings is included.

TABLE 33.—BLAST FURNACES, MINERAL FUEL—PRODUCTS, BY QUANTITY AND VALUE, CLASSIFIED ACCORDING TO KIND OF FUEL USED: 1880 TO 1905.

KIND.	1905		1900		1890		1880	
	Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.
Aggregate		$224,433,959		$200,676,934		$133,685,378		$76,739,573
Total pig iron	16,214,123	221,918,031	14,095,675	200,441,796	8,251,693	133,655,273	2,987,235	75,715,266
Coke and bituminous coal pig iron	14,909,029	203,814,049	12,253,818	173,763,091	6,265,865	100,687,256	1,354,958	35,513,233
Mixed anthracite coal and coke pig iron	1,274,721	17,712,934	1,796,000	26,066,003	1,690,394	28,195,996	638,027	16,627,291
Anthracite coal pig iron	30,373	391,048	45,857	612,702	295,434	4,772,021	994,250	23,574,742
All other products		2,515,928		235,138		30,105		1,024,307

Pig iron made with mixed anthracite coal and coke declined 521,279 tons from 1900 to 1905, or 29 per cent. The gain is all in bituminous pig iron, which increased in quantity 2,655,211 tons, or 21.7 per cent, and in value $30,050,958, or 17.3 per cent. The production of pig iron with anthracite coal alone has practically ceased; the last trace of it appears in the small product of 30,373 tons. The quantity of pig iron made with mixed anthracite and coke fuel is a little less than twice the quantity produced in 1880, and bituminous pig iron, chiefly coke, has increased more than tenfold. The amount reported for "all other products," aggregating $2,515,928 in 1905, includes castings made in foundries by blast furnace establishments, granulated slag, slag used for ballast, cement from furnace slag, as well as receipts for custom work and repairing. The last mentioned item was $324,996. Castings produced direct from furnace, as well as spiegeleisen and ferromanganese, are included in the pig iron product.

The average value of coke and bituminous coal pig iron was $13.67 per ton in 1905, $14.18 in 1900, $16.07 in 1890, and $26.21 in 1880; for mixed anthracite and coke pig iron the average price was $13.90 per ton in 1905, $14.51 in 1900, $16.68 in 1890, and $26.06 in 1880; and for pig iron made with anthracite coal alone, $12.87 per ton in 1905, $13.36 in 1900, $16.15 in 1890, and $23.71 in 1880.

Table 34 shows, by states, the production, value, and average value per ton of all kinds of mineral fuel pig iron for 1880, 1890, 1900, and 1905, and the number of completed furnaces for each of the years.

TABLE 34.—*Blast furnaces, mineral fuel—quantity and value of pig iron, with average value per ton, by states: 1880 to 1905.*

STATE.	Census.	Number of completed furnaces.	Tons.	Value.	Average value per ton.
United States	1905	380	[1] 16,214,123	[1] $221,918,031	$13.69

	1900	139	6,774,243	101,435,404	14.97
	1890	206	4,330,470	74,811,310	17.28
	1880	233	1,692,992	43,760,395	25.85
Tennessee [4]	1900	11	318,716	3,856,913	12.10
	1890	12	218,339	2,702,548	12.38
	1880	5	36,963	637,757	17.25
Virginia [4]	1900	21	426,501	6,459,970	15.15
	1890	13	271,831	3,755,651	13.82
	1880	7	7,515	168,120	22.37
West Virginia [4]	1890	5	115,508	2,009,505	17.40
	1880	6	70,298	1,580,096	22.48
Wisconsin [4]	1900	5	182,291	2,369,362	13.00
	1890	4	107,981	1,620,117	15.00
	1880	3	60,306	1,688,548	28.00
All other states	[6] 1905	176	5,985,043	77,559,179	12.96
	[7] 1900	22	741,006	11,107,448	14.99
	[8] 1890	19	154,877	2,602,647	16.80
	[9] 1880	21	98,084	2,419,563	24.67

[1] Includes 9,469 tons of direct castings, valued at $131,700, and 227,648 tons of spiegeleisen and ferromanganese, valued at $6,084,247.
[2] Includes 7,113 tons of direct castings, valued at $87,541, and 215,550 tons of spiegeleisen and ferromanganese, valued at $5,871,955.
[3] Includes 3,508 tons of direct castings, valued at $131,248.
[4] Included in "all other states" in 1905.
[5] Included in "all other states" in 1900 and 1905.
[6] Includes states as follows: Alabama, Colorado, Georgia, Kentucky, Maryland, Michigan, Minnesota, Missouri, Ohio, Tennessee, Virginia, West Virginia, Wisconsin.
[7] Includes states as follows: Colorado, Georgia, Kentucky, Maryland, Minnesota, Missouri, North Carolina, West Virginia.
[8] Includes states as follows: Colorado, Georgia, Indiana, Kentucky, Maryland.
[9] Includes states as follows: Georgia, Indiana, Kentucky, Maryland, Massachusetts.

The highest value per ton of mineral fuel pig iron reported was for Colorado, and the lowest for Georgia. For the states reported in detail the highest value per ton was for Illinois. The values for New York, West Virginia, New Jersey, Ohio, and Pennsylvania conform very closely to the averages for the country at large.

The only states showing an increase in the average value per ton are Alabama, Illinois, and Wisconsin, the apparent increase in the latter two states being large. But attention has already been called to probable error in the 1900 figures for Illinois.

DRY-AIR BLAST.

The most important improvement of late years in the blast furnace industry, and by some claimed not to be equaled by any improvement since Neilson's invention of the hot blast, is the Gayley dry-air blast, installed at the Isabella furnaces of the Carnegie Steel Company.

It had long been suspected that the moisture of the air, varying from day to day, between day and night, and even from hour to hour, was a prime cause of the irregular workings of a blast furnace, and the extent of the part played by moisture is strikingly shown by the comparative tests with dry-air blast and natural blast made at the aforesaid furnaces. The desiccation of the air is effected by passing it through a refrigerating chamber before it goes to the blowing engines and stoves. The furnace takes approximately 40,000 cubic feet of air per minute, and to handle this amount a refrigerating chamber of about 44,000 cubic feet capacity is used, filled with coils of 2-inch pipe, through which circulates the cold brine. This chamber has 90,000 feet of pipe, or over 17 miles. The moisture is deposited on the coils as ice and frost, and is periodically removed, after clearing the coils of the cold brine, by washing them down with a hose. The chamber is divided into four sections, one of which is cleared of ice each day.

When the plant was visited on a clear day in July in 1906, there was being removed 4.59 grains of moisture per cubic foot of air. At the rate of 40,000 cubic feet of air per minute, this is equivalent to 4,534 gallons of water per twenty-four hours, or a little over 18 tons of water, which, if running on natural air, would have gone into the furnace to consume heat energy.

When it is considered that the humidity of the air varies from half a grain per cubic foot on a cold, clear day in winter to 8 or even 9 grains on a muggy day in summer, the fluctuating character of this disturbing element can be readily appreciated.

The economies effected by the use of the dry-air blast are—reduction in fuel consumed per unit of pig iron of some 20 per cent; increase in the capacity of the furnace; reduction in iron ore waste (dust); and control over silicon range.

There is also, incidentally, a saving in power, as the combined power required for the desiccating plant and blowing engine when running on dry-blast is less than that consumed by the blowing engine when running with natural air. This difference is due to the fact that with dry-blast the blowing engine receives its air at 20° temperature and much condensed in volume, and the blast pressure required is less, the furnace being run with 13.5 pounds on dry-blast as against 15 pounds or more with natural air.

The following comparative statement shows the operations of the Isabella furnaces, Nos. 1 and 3, under dry air and natural air:

FURNACE.	Date.	Average daily product (gross tons).	Average amount of coke used per ton of pig iron (pounds).	Number of revolutions of blowing engine per minute.	Average temperature of hot blast (degrees).
No. 1: Dry air	November, 1904	447	1,816	96	854
No. 3: Natural air	November, 1904	386	2,279	111	750
No. 1: Dry air	January 1 to January 10, 1905.	428	1,825	96	869
Natural air	January 15 to January 31, 1905.	414	2,340	111	771
No. 3: Dry air	January 15 to January 31, 1905.	432	1,811	96	802
Natural air	January 1 to January 10, 1905.	410	2,351	111	716

This shows for the month of November a saving of 20.3 per cent in coke consumption per ton of pig iron, with an increase of 15.8 per cent in output, through the use of the dry-blast.

In January there is shown a saving of 22 per cent in coke per ton of pig iron, with an increase of 3.4 per cent in output for one furnace, and a saving of 23 per cent in coke and an increase of 5.4 per cent in output for the other furnace, through the use of the dry-blast.

Average gas analyses are given as follows:

	CO (per cent).	CO_2 (per cent).	Temperature (degrees).
Without dry-blast	22.3	13.0	538
With dry-blast	19.9	16.0	376

The reduction of 162 degrees in gas temperature is due to greater concentration of heat in the hearth and the greater weight of burden heated by the gas.

The following is a statement of the normal charge with natural air and with dry-air blast:

CHARGE.	Natural air.	Dry-air blast.
Ore:		
Pounds	20,000	24,000
Per cent of charge	55.9	60.0
Limestone:		
Pounds	5,600	5,800
Per cent of charge	15.6	14.5
Coke:		
Pounds	10,200	10,200
Per cent of charge	28.5	25.5

THE MANUFACTURE OF CHARCOAL PIG IRON.

The leading statistics of the manufacture of charcoal pig iron are shown in Table 35 for the census years 1880, 1890, 1900, and 1905.

TABLE 35.—BLAST FURNACES, CHARCOAL—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1880 TO 1905.

	CENSUS.				PER CENT OF INCREASE.		
	1905	1900	1890	1880	1900 to 1905	1890 to 1900	1880 to 1890

Value of products	$7,455,167	$5,344,515	$11,957,775	$12,575,996	39.5	[1]55.3	[1]4.9
Tons of pig iron	414,171	303,567	593,492	388,677	36.4	[1]48.9	52.7

[1] Decrease.
[2] Includes value of rented property—1905, $629,683; 1900, $273,800; 1890, $253,588.
[3] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Not reported.

The product for 1905 shows an advance over that for 1900, but it is not up to the product of 1890 and is less by 14,408 tons than the average for the years 1880, 1890, and 1900. In 1854 the charcoal pig iron product was 305,623 tons, and it constituted over one-half of the pig iron product of the country, whereas now, after the progress of half a century, it forms less than one-fortieth of the total product.

The capital investment, cost of production as shown by the items reported, and value of products per ton of pig iron for the charcoal industry is shown by the following tabular statement for the years 1890, 1900, and 1905:

	1905	1900	1890
Capital	$25.75	$20.28	$29.70
Expenses	16.23	13.99	18.43
Salaries	0.65	0.57	0.59
Wages paid	2.36	1.85	2.02
Miscellaneous expenses	0.95	0.86	1.70
Cost of materials used	12.27	10.71	14.12
Products	18.00	17.61	20.15

The labor item in 1890 constituted 11 per cent of the total cost per ton; in 1900, 13.2 per cent; and in 1905, 14.5 per cent. In this respect the charcoal pig iron industry differs from the mineral fuel branch, where the item of labor shows a reduction, on account of the general use of large furnaces and improved appliances for charging, machine casting, and for handling material economically.

The same states, 14 in number, that appeared as producers of charcoal pig iron in 1900 were also producers in 1905. Michigan continues to be the heaviest producer. In 1905 all of its charcoal furnaces were active, and the value of products was nearly double that of 1900 and considerably in excess of 1890. Wisconsin, Georgia, New York, and Alabama, in the order named, follow Michigan as producers of charcoal pig iron, though the Michigan charcoal iron product was nearly seven and a half times that of any other state.

Capital.—Table 36 shows the capital investment in all charcoal blast furnace establishments, active and idle, for the census years 1880, 1890, 1900, and 1905.

There has been a decrease of 11 in the number of establishments from 1900 to 1905, though the decrease is not relatively as large as that for the former census periods. The capital investment has increased 27.5 per cent. The active and idle establishments reported, all told, 55 completed charcoal stacks in 1905 of a total daily capacity of 2,540 tons, of which 20, having a capacity of 692 tons, were idle throughout the year.

TABLE 36.—*Blast furnaces, charcoal—active and idle establishments—capital: 1880 to 1905.*

	Census.	Number of establishments.	CAPITAL. Total.	Buildings, machinery, tools, and implements.	Land, cash, and sundries.
Total	1905	51	[1] $13,293,773	$5,304,501	$7,989,272
	1900	62	[1] 10,429,344	4,454,086	5,975,258
	1890	116	[1] 19,674,167	8,828,233	10,845,934
	1880	212	27,830,547	7,041,659	20,788,888
Active	1905	33	10,664,046	3,680,223	6,983,823
	1900	32	6,155,839	2,159,026	3,996,813
	1890	83	17,626,312	7,437,083	10,189,229
	1880	116	19,268,747	4,663,159	14,605,588
Idle	1905	18	2,629,727	1,624,278	1,005,449
	1900	30	4,273,505	2,295,060	1,978,445
	1890	33	2,047,855	1,391,150	656,705
	1880	96	8,561,800	2,378,500	6,183,300

[1] Includes value of rented property—1905, $805,683; 1900, $324,500; 1890, $253,588.

Materials used.—Table 37 presents in detail the materials used in the manufacture of charcoal pig iron for each census beginning with 1880.

The consumption of iron ore, all domestic, increased 221,014 tons, or 37 per cent.

The increase in the consumption of charcoal was 11,038,382 bushels, the percentage of increase, 37.7 per cent, corresponding to that of the ore consumption. The consumption of flux, however, as reported shows a very small increase in quantity, less than 1 per cent, and consequently a much reduced consumption per ton of product.

TABLE 37.—BLAST FURNACES, CHARCOAL—MATERIALS USED, BY KIND, QUANTITY, AND COST: 1880 TO 1905.

KIND.	1905		1900		1890		1880

All other materials		424,093		386,968		56,707		959

[1] None reported.
[2] Domestic and foreign ores were not reported separately in 1880.
[3] Quantities in bushels.
[4] Includes 2,486,700 bushels of charcoal and its value, the cost of stumpage and labor being reported as expense in other tables.

Products.—Table 38 shows the quantity and value of the charcoal pig iron product for the census years 1880, 1890, 1900, and 1905. No spiegeleisen, ferro-manganese, or direct castings were reported as produced with charcoal fuel in 1905.

TABLE 38.—BLAST FURNACES, CHARCOAL—PRODUCTS, BY KIND, QUANTITY, AND VALUE: 1880 TO 1905.

KIND.	1905		1900		1890		1880

All other products	.....	395,663	.....	5,776	.....	65	.....	87,252

[1] Includes product of 1 penal institution.

[2] Not reported separately.

At the census of 1900 and prior censuses a report of the amounts of charcoal pig iron produced with hot or warm blast and with cold-blast, respectively, was called for, but as very little cold-blast charcoal pig iron is now made, this inquiry was dropped in making the canvass for the census of 1905. In 1900 only 4 per cent of the charcoal pig iron was made with cold-blast.

The increase in the quantity of charcoal pig iron product in 1905 over 1900 was 110,604 tons, or 36.4 per cent; and in value, exclusive of all other products, it was $1,720,765, or 32.2 per cent.

Table 39 shows the number of completed furnaces and the quantity, value, and average price per ton of charcoal pig iron for 1880, 1890, 1900, and 1905.

TABLE 39.—*Blast furnaces, charcoal—quantity and value of pig iron, with average value per ton: 1880 to 1905.*

STATE.	Census.	Number of completed furnaces.	Tons.	Value.	Average value per ton.
United States	1905	55	414,171	$7,059,504	$17.04
	1900	66	[1] 303,567	[1] 5,338,739	17.59
	1890	140	593,492	11,957,710	20.15
	1880	251	[2] 388,677	[2] 12,488,744	32.13

[1] Includes 10 tons of direct castings, valued at $121.
[2] Includes 300 tons of direct castings, valued at $14,988.

The average value per ton for charcoal pig iron is $17.04, compared with $17.59 in 1900.

At the census of 1900 the manufacture of pig iron with mixed charcoal and coke fuel was reported by 6 establishments—4 in Tennessee, which used this mixed fuel exclusively; 1 charcoal furnace in Ohio; and 1 coke furnace in Georgia, which made small quantities of pig iron with this fuel.

The manufacture of pig iron with mixed charcoal and coke has now been abandoned, and of the establishments above referred to, 4 made coke pig iron in 1905, 1 made charcoal iron, and 1 was idle.

STEEL WORKS AND ROLLING MILLS.

Table 40 shows the leading statistics for steel works and rolling mills for each census year, 1870 to 1905.

The number of active steel works and rolling mills from which separate reports were received shows a decrease of 23 from the number in 1900. In some cases, however, two or more plants under one and the same ownership and within the same municipality are covered by one report in 1905, and thus figure as one establishment, where in 1900 separate reports were made for the different plants. The number of establishments as here reported means the number of reports received and tabulated.

TABLE 40.—STEEL WORKS AND ROLLING MILLS—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1870 TO 1905.

	CENSUS.					PER CENT OF INCREASE.			
	1905 [1]	1900	1890	1880	1870 [2]	1900 to 1905	1890 to 1900	1880 to 1890	1870 to 1880

[1] Exclusive of the statistics of 6 establishments engaged primarily in the manufacture of other products. These establishments made 4,184 tons of steel castings, valued at $347,264.
[2] Includes idle establishments which were not reported separately in 1870.
[3] Decrease.
[4] Includes value of rented property—1905, $8,948,336; 1900, $11,835,940; 1890, $3,212,000.
[5] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[6] Not reported separately.
[7] Not reported.

Certain manufacturers in other lines of industry have equipments for the manufacture of steel or rolled material for use in their own establishments in the production of machinery or other constructions. Establishments of this kind reported as partial products in 1905, 4,184 tons of direct steel castings, of a value of $347,264, and these figures must be added to the above table in order to find the total products of steel works and rolling mills. Where a separate report for the steel or rolling mill section of such an establishment was not obtainable, the iron or steel products of this section do not figure in these tables, but enter into the report of the active operations of the establishment, which is classified according to the nature of the finished products. The steel making and rolling mill equipments of such establishments are shown in the tables which give the equipment of all establishments.

Table 41 shows the statistics, by states, of the active establishments which produced steel ingots or castings and hot-rolled iron and steel for 1880, 1890, 1900, and 1905.

TABLE 41.—STEEL WORKS AND ROLLING MILLS—COMPARATIVE SUMMARY, BY STATES: 1880 TO 1905.

[1] Included in "all other states" in 1905.
[2] Included in "all other states" in 1890.
[3] Includes establishments distributed as follows: Colorado, 1; Georgia, 1; Kansas, 1; Maine, 1; Oregon, 1; Rhode Island, 4; Tennessee, 2; Washington, 1.
[4] Includes establishments distributed as follows: Colorado, 2; Kansas, 1; Maine, 1; Minnesota, 2; Oregon, 1; Rhode Island, 1; Washington, 1; Wyoming, 1.
[5] Includes establishments distributed as follows: Colorado, 1; Georgia, 1; Iowa, 1; Maine, 1; Minnesota, 1; New Hampshire, 1; Rhode Island, 1; Wisconsin, 1; Wyoming, 1.
[6] Includes establishments distributed as follows: Colorado, 1; District of Columbia, 1; Georgia, 1; Kansas, 2; Maine, 2; Nebraska, 1; New Hampshire, 2; Rhode Island, 1; Vermont, 1; Wyoming, 1.

There were 26 states reporting in 1905, compared with 27 states in 1900 and 1890, and 29 in 1880. Minnesota has 2 establishments, of which 1 was idle in 1905 and the other produced steel castings which were consumed by the establishment in manufactures. The rolling mill in Wyoming was idle in 1905. Georgia has resumed the manufacture of rolled iron and steel products. There were 27 states, all told, making steel and rolling mill products, including Minnesota, which manufactured a small amount of steel in an establishment otherwise classified.

Pennsylvania continues to produce more than one-half of the cast steel and rolled iron and steel products, its output in 1905 constituting 54 per cent of the total value, compared with 55.7 per cent in 1900, with 56.9 per cent in 1890, and with 48.4 per cent in 1880. This

state reports over one-half of the capital and one-half of all employees and expenses pertaining to the industry. Its present share of the steel making and rolling mill industry is even greater than its share of the blast furnace branch, and exceeds by over $30,000,000 the total product of steel works and rolling mills for the entire country in 1890.

Ohio ranks second, with an increase of 13.6 per cent; Illinois third, with an increase of 32.9 per cent, and New York fourth, with an increase of 144 per cent. A decrease in the value of products, compared with 1900, appears in Delaware, Indiana, Massachusetts, Michigan, Missouri, New Jersey, and Virginia.

CAPITAL.

The capital invested in steel works and rolling mill establishments, active and idle, for 1880 to 1905, is shown in Table 42.

TABLE 42.—*Steel works and rolling mills—active and idle establishments—capital: 1880 to 1905.*

	Census.	Number of establishments.	CAPITAL. Total.	Buildings, machinery, tools, and implements.	Land, cash, and sundries.
Total	1905	494	[1]$730,378,292	$417,216,418	$313,161,874
	1900	476	[1]449,926,470	214,025,431	235,901,039
	1890	429	[1]284,271,524	132,989,177	151,282,347
	1880	391	120,522,745	71,567,596	48,955,149
Active	1905	415	709,130,646	400,038,881	309,091,765
	1900	438	441,795,983	208,249,924	233,546,059
	1890	395	278,559,831	128,623,160	149,936,671
	1880	358	116,458,300	69,033,147	47,425,243
Idle	1905	79	21,247,646	17,177,537	4,070,109
	1900	38	8,130,487	5,775,507	2,354,980
	1890	34	5,711,693	4,366,017	1,345,676
	1880	33	4,064,355	2,534,449	1,529,906

[1] Includes value of rented property—1905, $9,027,956; 1900, $11,888,815; 1890, $3,230,000.

The capital invested in steel works and rolling mills constitutes 73.6 per cent of that employed in the iron and steel industries; substantially the same proportion as in 1900, when it represented 73.9 per cent of the aggregate capital.

The increase in the total capital invested in steel works and rolling mills from 1900 to 1905 was $280,451,822, or 62.3 per cent, as compared with the increase for the decade from 1890 to 1900 of $165,654,946, or 58.3 per cent. Of the aggregate capital reported in 1905, 97.1 per cent was invested in active establishments and 2.9 per cent in idle, as compared with an investment of 98.2 per cent of the total capital in 1900 in active establishments, and 1.8 per cent in idle. Of the total capital in 1905, 57.1 per cent was in buildings, machinery, tools, and implements and 42.9 per cent in lands, cash, and sundries; compared with 47.6 per cent in the former and 52.4 per cent in the latter in 1900. The increase of investment in equipment is thus shown to have been relatively much greater than the investment in land and active capital.

The idle establishments, 79 in number, were located in the following states: Alabama, 2; Delaware, 1; Illinois, 2; Indiana, 13; Kentucky, 1; Massachusetts, 2; Minnesota, 1; Missouri, 1; New Jersey, 2; New York, 5; Ohio, 10; Pennsylvania, 33; Virginia, 1; West Virginia, 1; Wisconsin, 3; and Wyoming, 1. The capital invested in idle establishments shows an increase of $13,117,159 over that in 1900.

The 7 forges and bloomeries, 6 active and 1 idle, which are included with the steel works and rolling mills, but are not equipped with hot rolls, are all that is left of a once large industry. They have a reported capital of $256,639, of which $70,681 is for buildings, machinery, tools, and implements, and $185,958 for land, cash, and sundries.

MATERIALS USED.

Table 43 shows the quantity and cost of the principal materials used by steel works and rolling mills in 1880, 1890, 1900, and 1905, and the percentage of increase, both in tonnage and value.

The statistics for 1900 showed a decline in the use of iron ore by rolling mills, due chiefly to the dismantling of puddling furnaces, but the returns for 1905 show an increase which a little more than makes up this decrease. The consumption of pig iron, spiegeleisen, and ferromanganese has increased 1,780,947 tons; old iron or steel rails and other scrap iron and steel, 1,010,990 tons; purchased hammered iron-ore blooms, pig or scrap blooms, and imported Swedish billets and bars, 49,249 tons; purchased muck bar or scrap bar, 44,622 tons; purchased iron or steel ingots, blooms, billets, tin-plate bars, sheet bars, or slabs, 949,850 tons; and purchased wire rods, 25,189 tons.

At the census of 1900 the total amount and kind of fuel consumed was reported, but no separation was made between fuel used for power and that used for melting and heating purposes. In making the canvass for the present census an inquiry was made of the cost of fuel used for power. As the character of the fuel reported as used for power purposes does not appear in the returns, the total amount of fuel by kinds can not be given, and hence no comparison can be made between 1905 and 1900 of the consumption of fuel by kinds, but only of the cost of all fuel used. This shows an increase since 1900 of $12,850,571, or 57.5 per cent.

TABLE 43.—STEEL WORKS AND ROLLING MILLS—MATERIALS USED, BY KIND, QUANTITY, AND COST, WITH PER CENT OF INCREASE: 1880 TO 1905.

KIND.	CENSUS.								PER CENT OF INCREASE.

[1] Decrease. [2] Not reported separately. [3] Short tons. [4] Bushels. [5] Barrels.

The use of oil as fuel in 1905 by steel works and rolling mills, in whole or in part, was reported by 16 states. Illinois was the largest user. Natural gas was used in 5 states, and by 109 establishments, distributed as follows: Pennsylvania, 69; Ohio, 22; Indiana, 9; West Virginia, 8; and Kentucky, 1. The cost of natural gas used as fuel in 1905 shows an increase of $1,284,258, or 41.4 per cent. In 1900 natural gas was used by 92 establishments and in 1890 by 85. The establishments using natural gas show an increase of 8 in Pennsylvania, 14 in Ohio, 3 in West Virginia, and a decrease of 8 in Indiana. The cost of natural gas consumed in Pennsylvania in 1905 shows an increase of $773,737, or 29.7 per cent, over 1900; in Ohio it shows an increase of $523,943, or 407.8 per cent; in West Virginia, an increase of $124,914, or 165 per cent; and in Kentucky, an increase of $20,949, or 611.1 per cent; while in Indiana the decrease is $159,285, or 56.3 per cent.

PRODUCTS.

Table 44 shows the quantity and value of the leading products reported by the steel works and rolling mills for 1880, 1890, 1900, and 1905.

TABLE 44.—STEEL WORKS AND ROLLING MILLS—PRODUCTS, BY KIND, QUANTITY, AND VALUE: 1880 TO 1905.

[1] Not reported separately. [2] None reported.
[3] Exclusive of 4,184 tons of steel castings, valued at $347,264, made by establishments engaged primarily in the manufacture of other products.

The above table gives the chief products comparable for the different census years. The products shown in detail aggregate 17,291,328 tons at the census of 1905, as compared with 14,467,737 tons for 1900. The total classified product of steel works and rolling mills in 1905 was 18,216,639 tons, as shown by Table 45, compared with 15,040,129 tons in 1900 (an increase of 21.1 per cent), and with 7,388,244 tons in 1890 and 3,046,038 tons in 1880.

Table 45 is a detailed summary of the products for 1905.

[1] Short tons [2] Kegs of 100 pounds. [3] Pounds.

Iron and steel rails.—The total production of iron and steel rails was 2,194,605 tons, as compared with 2,251,337 tons in 1900, a slight decrease in tonnage. This does not include rails renewed or rerolled. Bessemer steel rails amounted to 2,065,024 tons and open-hearth steel rails to 128,681 tons. In 1900 the open-hearth steel rails made did not exceed 1,500 tons and in 1890 no open-hearth steel rails were made.

The average value of steel rails, as obtained from these reports, was $26.55 per ton in 1905, $20.66 per ton in 1900, $32.51 per ton in 1890, and $56.54 per ton in 1880. It should be stated that the Census report of

1900 was for the fiscal year ending June 30, 1900, or the business year of the establishment nearest conforming thereto. During the year 1899 there was a very wide fluctuation in prices for Bessemer steel rails, the average monthly prices, as reported by the American Iron and Steel Association, ranging from $18.50 per ton in January, 1899, to $35 per ton in December, and resulting in an average for the year of $28.12. The values as reported by the different producers in 1900 show a like wide range, from less than $18 per ton for Illinois to nearly $30 per ton for Ohio, and result in a low average for the country at large. Since the early part of 1901 the quoted price for steel rails at the mills, as reported by the American Iron and Steel Association, has been uniform at $28 per ton.

In 1905 steel rails were produced by 14 establishments. Bessemer steel rails were made by 12 establishments and open-hearth steel rails by 5.

In addition there were 8 establishments which did not manufacture new rails, but which renewed or rerolled rails, making 22 establishments in the aggregate that rolled rails. Two of the establishments that manufactured rails also rerolled or renewed rails. The total amount renewed or rerolled was 104,429 tons, of which 99,530 tons were reported as of a value of $2,480,328 and 4,899 tons were rerolled on toll.

Pennsylvania produced 812,691 tons of rolled rails, chiefly Bessemer, a little less than three-eighths of the entire product; in 1900 its production was over one-half of the total. Illinois ranks second, its production being all Bessemer. New York is third and Maryland fourth, with Bessemer steel rails in each case; Alabama, not a producer of steel rails in 1900, is fifth, its rail product being of open-hearth steel; and Ohio sixth, with all Bessemer steel rails. Only 900 tons of iron rails were reported.

Splice bars.—Splice bars, including all patent splices and rail joints, to the extent of 174,055 tons were reported at the census of 1905, of an average value of $32.54 per ton. In 1900 these products were not specifically reported but were included under miscellaneous rolled products, and their value was included in that for "all other products." Pennsylvania made more than one-half of this class of products, 93,043 tons, and Illinois, with 54,978 tons, was the second largest producer.

Bars and rods.—The production of iron and steel bars and rods, not including wire rods, shows a slight decrease in quantity from 1900, namely, 2 per cent, and a decrease of 16.4 per cent in value. The average value in 1905 was $34.41 per ton; in 1900 it was $40.35 per ton; in 1890, $43.61 per ton; and in 1880, $64.86 per ton. In the figures given for 1890 and 1880 only the quantity and value of bars and rods manufactured for sale were given. In 1900 and for the present census the quantity and value are given of all bars and rods made, whether sold as products or consumed by the establishment in the manufacture of other products. The increased value given to bars and rods when manufactured into bolts, nuts, etc., by the rolling mill establishment has been included under "all other products."

The average value shows a decline of 14.7 per cent from the average for 1900. This is in harmony with the general decline in the average value per ton of all classified products of steel works and rolling mills, which fell from $33.94 in 1900 to $32.08 in 1905, or 5.5 per cent. Products in this group were made in all states having rolling mills except Georgia, Kansas, and West Virginia. Of the leading states, Pennsylvania made 1,166,234 tons, nearly one-half of the total amount, of an average value of $34.66 per ton; Ohio, Indiana, and Illinois produced, respectively, 274,191 tons, 212,421 tons, and 145,527 tons; the average value per ton in these states, in the order named, being $31.63, $31.62, and $32.52.

Wire rods.—Wire rods show the heaviest increase of any of the groups of products, the increase in tonnage being 876,172 tons, or 95.6 per cent, and in value, $17,465,502, or 49.2 per cent. The average value in 1905 was $29.96 per ton, and in 1900, $38.76.

The manufacture of wire rods is reported by 11 states—Pennsylvania, Ohio, Illinois, Massachusetts, Indiana, Kentucky, Colorado, New York, New Jersey, Alabama, and Rhode Island. Of the leading states, Pennsylvania turned out 596,892 tons, of an average value of $28.36 per ton. With two exceptions the output of the other states was in each state the product of less than 3 establishments.

Structural shapes.—Structural shapes in the aggregate have increased from 856,983 tons in 1900 to 954,537 tons in 1905, or 11.4 per cent. The average value for all shapes has remained substantially the same, $34.26 per ton in 1900 and $34.29 per ton in 1905. Iron shapes in 1905 averaged $32.45 per ton; Bessemer steel, $33.43 per ton; and open-hearth steel, $34.76 per ton. Iron shapes were reported from California and Pennsylvania. Bessemer steel structural shapes were reported for Pennsylvania, Illinois, Ohio, and Wisconsin, in the order named as to quantity of product, and open-hearth steel shapes from Pennsylvania, New Jersey, Indiana, Wisconsin, New York, Colorado, Ohio, and Alabama. Pennsylvania produced more than six-tenths of the total quantity of steel structural shapes, or 822,618 tons, of which 546,440 tons were open-hearth steel; New Jersey was the next largest producer, followed by Illinois, and then by Ohio.

Iron and steel hoops, bands, cotton ties, and skelp.—The production of hoops, bands, cotton ties, and skelp in 1905 amounted to 1,894,913 tons, of a value of $59,540,212, an increase from 1900 of 699,724 tons, or 58.5 per cent, in quantity and of $10,380,465, or 21.1 per cent, in value. The production of skelp, the chief item of this group, amounted in 1905 to 1,557,690

tons, and hoops, bands, and cotton ties to 337,223 tons. In 1900 the production of skelp was not reported separately. The average value of all products of this group in 1905 was $31.42 per ton, compared with $41.13 per ton for 1900. The average value for skelp in 1905 was $30.03 per ton.

Hoops, bands, and cotton ties were reported in 1905 from Pennsylvania, Ohio, Illinois, Georgia, Massachusetts, and Alabama; Pennsylvania produced 200,461 tons; Ohio, 102,823 tons; and the other 4 states, the remaining 33,939 tons. Skelp was produced by Pennsylvania to the extent of 1,058,588 tons, or two-thirds of the product of the country. Ohio made 211,624 tons; West Virginia, 192,644 tons; and Illinois, Connecticut, and New York produced the remaining 94,834 tons.

Car axles.—In 1905 only 631 tons of rolled car axles were reported, whereas in 1900 the production amounted to 2,229 tons.[1] Iron and steel hammered car axles were reported from Pennsylvania, Michigan, Illinois, California, and Ohio in 1905 to the extent of 82,954 tons, of an average value of $34.35 per ton. In 1900, 100,377 tons of hammered car axles, of an average value of $43.78 per ton, were manufactured by Pennsylvania, Missouri, Michigan, Virginia, Alabama, New Jersey, and Delaware. Pennsylvania produced 88.5 per cent of the hammered car axles in 1905, compared with 78.9 per cent in 1900.

Muck and scrap bar produced for sale.—The muck and scrap bar shown in the table does not include that made and consumed by the producing establishments in the manufacture of more highly finished rolled products. Muck or scrap bar, to be marketed as such, was reported from Pennsylvania, Ohio, Indiana, and Delaware to the extent of 150,926 tons; more than two-thirds of this was from Pennsylvania, and one-fifth from Ohio. The average value of the product was $26.11 per ton at the census of 1905, and in 1900 it was $29.16 per ton.

Boiler and other plates and sheets, except nail and tack plates, black plates or sheets for tinning, and armor plate.—The production of iron and steel boiler and other plates, exclusive of nail and tack plates, black plates or sheets for tinning, and armor plate (which are reported separately), was reported by 13 states and shows an increase of 368,403 tons, or 24.8 per cent, in quantity and of $9,692,778, or 14.2 per cent, in value. The average value per ton was $41.91 at the census of 1905, $45.77 in 1900, $60.30 in 1890, and $85.60 in 1880. The bulk of the output was reported by Pennsylvania, which manufactured 1,297,086 tons, over two-thirds of the total, at an average value of $40.43 per ton; and from Ohio, which made 364,790 tons, one-fifth of the total, at an average value of $43.94 per ton. Other producing states were Illinois, the product being by less than three establishments; West Virginia, with 34,036 tons; Kentucky, 33,921 tons; Indiana, 23,947 tons; and in a lesser degree, Delaware, Missouri, Alabama, Connecticut, New York, New Jersey, and Maryland.

Nail and tack plate.—Nail plate was reported in 1905 by 10 states to the extent of 67,857 tons, of an average value of $26.92 per ton, compared with 81,101 tons in 1900, of an average value of $30.41 per ton. This shows a decrease in quantity of 16.3 per cent. More than one-half of the amount, namely, 37,162 tons, of an average value of $25.42 per ton, was made in Pennsylvania. West Virginia was the next in rank. Other states making nail plate were Colorado, Kentucky, Illinois, Ohio, Massachusetts, Indiana, California, and Virginia, named in the order of amount of product.

Tack plates were reported by 4 states—West Virginia, Massachusetts, Pennsylvania, and California. The average value for the 18,744 tons made was $33.89, compared with an average value of $39.26 for the 16,563 tons made in 1900. The increase in quantity was 13.2 per cent.

Black plates or sheets for tinning.—Prior to the stimulus given the tin and terne plate industry in this country by the tariff act of 1890, very few black plates or sheets for tinning were produced. In 1900 the total production as reported was 394,014 tons, of a value of $20,967,806, an average value of $53.22 per ton. At the census of 1905 the total amount was 504,025 tons, of a value of $25,297,079, an average of $50.19 per ton. This is an increase of 27.9 per cent in quantity over 1900, and of 20.6 per cent in total value of product. In 1900 there were 44 active black plate establishments. No iron black plates were reported by any of the establishments. The Bessemer black plates, constituting more than nine-tenths of the total production, averaged in 1900, $52.59 per ton and the open-hearth black plates, $58.93 per ton.

At the present census returns were made of black plates by 35 active establishments. Iron black plates were made by 6 establishments, Bessemer steel black plates by 25 establishments, and open-hearth steel black plates by 17 establishments.

Bessemer steel black plates show a slight decrease in quantity, while open-hearth steel black plates have more than doubled. The average value in 1905 for iron black plates was $43.83 per ton; for Bessemer steel, $51.76; and for open-hearth steel, $48.52—or for all grades, as before stated, $50.19 per ton.

The value per ton for open-hearth steel plates appears considerably less than for Bessemer steel, owing to the low valuation given in certain reports. The 12 establishments in Pennsylvania and Ohio producing open-hearth steel black plates, which made nearly one-half of the total product, show an average value per ton of $52.64. Pennsylvania,

[1] Error in Twelfth Census report consisting of the tabulation as "rolled car axles" of 1,592 tons of hammered car axles, of a value of $98,861, in New Jersey, and 52,518 tons of hammered car axles, of a value of $2,569,349, in Pennsylvania, has been corrected.

with 34,665 tons of iron black plates, more than one-half of the total amount, ranked first; it was followed by Ohio and West Virginia. Pennsylvania was also first in the production of Bessemer steel black plates, making 213,904 tons, nearly two-thirds of the total, followed by Indiana, Ohio, West Virginia, and Kentucky. In the manufacture of open-hearth steel black plates Illinois was first, followed by Ohio, Pennsylvania, Maryland, West Virginia, and Indiana.

Armor plate and gun forgings.—The product reported under armor plate and gun forgings is from 4 establishments—3 in Pennsylvania and 1 in New Jersey—a relatively small amount of gun forgings being reported. There is shown an increase in the total products of this group of 7,537 tons, or 49.3 per cent, in quantity and of $2,034,337, or 27 per cent, in value. The product in 1905 was of an average value per ton of $418.62, as compared with an average value per ton in 1900 of $491.86.

Rolled blooms, slabs, billets, tin-plate bars, and sheet bars produced for sale.—Much the larger part of this group appears again in the material of other rolling mills. The figures are comparable with those of 1900 only, as prior thereto the products of this group were not reported separately. The products show an increase of 651,299 tons in quantity, or 15.6 per cent, over those of 1900, and an increase of 13.8 per cent in value. At the census of 1905 the average value per ton was $22.72 and in 1900 it was $23.09.

The manufacture of these products for sale was reported by 12 states. Pennsylvania produced 2,582,848 tons, valued at $22.54 per ton, more than one-half of the total amount, and Ohio, 1,803,873 tons, valued at $22.37 per ton. Illinois reported 298,805 tons, and the remaining 138,059 tons were from Alabama, Kentucky, Indiana, Maryland, Connecticut, Colorado, Massachusetts, Rhode Island, and Delaware, the last 4 states marketing very small amounts.

Steel ingots produced for sale.—The total production of steel ingots was 13,379,083 tons, valued at $240,284,576. This is the total quantity of steel ingots made both for consumption by the producing establishments and for sale. Of this quantity, 196,404 tons, or less than 1.5 per cent, were produced for sale, the average value thereof being $20.29 per ton, as compared with an average value of $26.82 per ton in 1900. Much the larger part of the steel ingots sold becomes material for rolling mills purchasing steel ingots, though some of the ingots go to establishments manufacturing heavy forgings.

Of the ingots produced for sale, West Virginia and Pennsylvania reported all but 3 per cent. The production of steel ingots will be considered at length in subsequent tables.

Direct steel castings.—Direct steel castings to the amount of 287,325 tons and valued at $20,600,136, or an average value of $71.70 per ton, were reported in 1905. This is an increase of 62.2 per cent over the quantity reported in 1900, which was 177,156 tons, valued at $14,609,893, or an average of $82.47 per ton. Pennsylvania, with 26 establishments, produced 114,411 tons of direct steel castings, valued at $8,041,419, or an average of $70.29 per ton; Illinois, with 7 establishments, 56,038 tons, valued at $4,148,259, or an average of $74.03 per ton; New York, with 5 establishments, 35,605 tons, valued at $1,991,778, or an average of $55.94 per ton; Ohio, with 8 establishments, 35,156 tons, valued at $2,308,178, or an average of $65.66 per ton; New Jersey, with 4 establishments, 11,656 tons, valued at $1,406,317, or an average of $120.65 per ton; Wisconsin, with 8 establishments, 9,215 tons, valued at $848,230, or an average of $92.05 per ton; and Indiana, with 3 establishments, 8,709 tons, valued at $498,447, or an average of $57.23 per ton. Direct steel castings to the extent of 790 tons, not included in the above, were reported by 1 establishment in Indiana, classified as "foundry and machine shop products." The remaining 16,535 tons, valued at $1,357,508, were produced by 12 establishments distributed through the states of Missouri, Michigan, Connecticut, Alabama, Delaware, Tennessee, California, Colorado, and Rhode Island, named in the order of their production.

Direct steel castings are further shown in later tables.

Miscellaneous rolled products.—In 1905, 377,665 tons of miscellaneous rolled products were reported, comprising locomotive and car wheel tires, rolled blanks suitable for drawing into seamless tubes, flats, socket iron and steel, etc. The value of these was $16,743,727, an average per ton of $44.33. Pennsylvania produced 253,330 tons of these miscellaneous products; New York, 47,445 tons; Ohio, 33,825 tons; and New Jersey, 12,514 tons. Other material producers were Michigan, Connecticut, Kentucky, and California. No other state produced over 600 tons.

Miscellaneous forged, cast, or other iron and steel products.—The total production of forged, cast, or other miscellaneous iron and steel products, not otherwise specifically classified, amounted to 274,061 tons, of a value of $15,684,967, an average of $57.23 per ton. Included therein are light and heavy forgings, and miscellaneous iron and steel products, not rolled, and the product of the few remaining forges and bloomeries. The latter amounted to 5,626 tons, valued at $157,505, an average of $28 per ton.

Total production of steel castings and of rolled and forged iron and steel, by states.—Table 46 shows the total production by steel works and rolling mills of all kinds of rolled and forged iron and steel, including steel ingots produced for sale and direct steel castings, in 1880, 1890, 1900, and 1905, by states.

TABLE 46.—STEEL WORKS AND ROLLING MILLS—QUANTITY OF CLASSIFIED PRODUCTS, WITH PER CENT OF TOTAL, BY STATES: 1880 TO 1905.

STATE.	QUANTITY (TONS).				PER CENT OF TOTAL.			
	1905	1900	1890	1880	1905	1900	1890	1880

[1] Less than one-tenth of 1 per cent.
[2] The single rolling mill in this state was active in 1905 and 1900, but was engaged exclusively on custom work.

The production of steel works and rolling mills in 1905 shows an increase of 3,176,510 gross tons, or 21.1 per cent over the production of 1900, an average of 4.2 per cent per year; compared with an increase of 7,651,885 tons in 1900 over 1890, an average of 10.4 per cent per year, and with an increase of 4,342,206 tons in 1890 over 1880, an average of 14.3 per cent per year. Pennsylvania made more than one-half of the total production in 1905, 1900, and 1890, and nearly one-half in 1880. The maximum percentage of the total products was in 1890 and has since gradually decreased. Ohio made nearly one-fifth of the production in 1905, and its proportion of the total has shown a steady increase.

The states of Delaware, Maine, Michigan, and Virginia show a reduction in output for 1905 compared with 1900, and Minnesota and Wyoming, which were producers in 1900, had no production in 1905. Kansas does not appear as a producer in 1905 and 1900. Its single rolling mill was in operation in both years, but was employed on custom work and repairing. The heaviest relative growth was in New York and Alabama, the products of the former showing for 1905 an increase of 312.6 per cent over 1900, and of the latter state, an increase of 164.4 per cent.

MISCELLANEOUS SECONDARY PRODUCTS.

The production of cut nails and spikes, wire, wire nails, bolts, nuts, rivets, forged spikes, washers, wrought pipes or tubes, horse and mule shoes, springs, etc., when made by steel works or rolling mills, represents the manufacture into more highly finished forms of nail plate, wire rods, bars, skelp, or other rolling mill products already reported. The added value due to this higher finishing has been carried to "all other products," as before stated, the quantities and value of the nail plate, wire rods, skelp, etc., so used, being reported under their respective groups as rolling mill products.

Table 47 shows, for 1905, the quantity and value of the leading products of this group manufactured by rolling mills and the value of those manufactured by other establishments, together with the number of establishments producing each kind.

Nails.—There was reported in 1905 by rolling mills 1,311,549 kegs of cut nails and cut spikes, of a value of $2,394,108, an average value of $1.83 per keg, and 9,061,512 kegs of wire nails, of a value of $17,495,362, an average value of $1.93 per keg. Altogether 34 rolling mills reported the manufacture of nails, 17 of which made cut nails and spikes and 21, wire nails. The total nail product of rolling mills, 10,373,061 kegs, was valued at $19,889,470, an average value of $1.92 per keg.

The manufacture of iron and steel nails and spikes, cut and wrought, including wire nails, was reported by 83 establishments not equipped with hot rolls, the

value of their products amounting to $12,940,726. The total value of all iron and steel nails and spikes, cut and wrought, including wire nails, was $32,830,196. This was the output of 117 establishments.

The production of nails by establishments other than rolling mills comprises the product of 76 establishments, classified as "iron and steel, nails and spikes, cut and wrought, including wire nails, not made in rolling mills or steel works," amounting to $8,922,896, and the wire nail product of 7 establishments, classified as "wire," which made wire nails of the value of $4,017,830, or a total value of $12,940,726.

TABLE 47.—STEEL WORKS AND ROLLING MILLS—PRINCIPAL IRON AND STEEL MISCELLANEOUS SECONDARY PRODUCTS OF ROLLING MILLS AND ESTABLISHMENTS OTHER THAN ROLLING MILLS: 1905.

KIND.	TOTAL.		ROLLING MILLS.			ESTABLISHMENTS OTHER THAN ROLLING MILLS.	
	Number of establishments.	Value.	Number of establishments.	Quantity.	Value.	Number of establishments.	Value.
Nails and spikes, total	117	$32,830,196	34	[1] 10,373,061	$19,889,470	83	$12,940,726
Cut nails and cut spikes			17	[1] 1,311,549	2,394,108		[2]
Iron			8	[1] 206,615	400,846		[2]

Combined iron and steel			11	[1] 144,264	261,198		[2]
Wire nails			21	[1] 9,061,512	17,495,362		[2]
Iron and steel wire and wire products of wire-drawing mills, not including wire nails, total	41	65,858,594	25	[3] 963,419	50,056,081	16	15,802,513
Wire			25	[3] 624,298	30,992,672		[2]
Other wire products			12	[3] 339,121	19,063,409		[2]
Iron and steel bolts, nuts, rivets, forged spikes, washers, etc.	118	28,138,607	30	[4] 277,306	13,854,635	88	14,283,972
Iron and steel wrought pipe or tubes	27	59,527,178	14	[4] 849,047	43,985,728	13	15,541,450
Iron and steel seamless-drawn, clinched, brazed, etc., pipe or tubes	23	4,149,696	8	[4] 20,636	2,290,234	15	1,859,462
Horse and mule shoes	19	6,282,118	11	[4] 68,594	5,483,137	8	798,981
Iron and steel springs, car, carriage, furniture, etc.	61	7,449,468	9	[4] 22,022	1,708,632	52	5,740,836

[1] Kegs. [2] Not reported separately. [3] Short tons. [4] Tons.

The products of the establishments included in the industry classified as "iron and steel, nails and spikes, cut and wrought, including wire nails, not made in rolling mills or steel works" were in detail as follows:

Total	$8,922,896
Wire nails	2,787,159
Horse nails	2,345,762
Tacks and small nails	1,664,161
Shoe tacks and shoe nails	988,144
Cut nails	218,056
Spikes, etc	72,285
Miscellaneous products	847,329

The value of the wire nails made by these establishments ($2,787,159), combined with that of the wire nail products of the classified "wire" industry ($4,017,830), makes a total of $6,804,989 as the value of the wire nails made by establishments other than rolling mills, and this combined with the wire nail product of the rolling mills gives a total of $24,300,351 as the value of all iron and steel wire nails. The total production of cut nails and spikes, not including tacks and small nails, amounted to $2,684,449.

The quantity made by establishments other than rolling mills was not reported, but estimated on the basis of $1.83 per keg for cut nails and spikes and $1.93 per keg for wire nails—the average values for rolling mills—the cut and wire nail product of these establishments (not including wrought nails, tacks, and small nails) would be 3,684,557 kegs. The total product was thus approximately 14,057,000 kegs.

The total nail product by kinds, so far as it can be itemized, is as follows:

KIND.	Quantity (kegs).	Value.
Total		$32,830,196
Wire nails	12,587,000	24,300,351
Cut nails and cut spikes	1,470,000	2,684,449
Horse nails		2,345,762
Tacks and small nails		1,664,161
Shoe tacks and shoe nails		988,144
Miscellaneous products		847,329

Rolling mill establishments making cut and wire nails were distributed as follows: Pennsylvania, 13; Illinois, 3; Indiana, Massachusetts, Ohio, and West Virginia, 2 each; and Alabama, California, Colorado, Connecticut, Kentucky, New York, Rhode Island, Virginia, 1 each. The other establishments making these are distributed as follows: Massachusetts, 37 (including 1 wire-drawing mill); Pennsylvania, 8; New York, 7; Illinois, 10 (including 4 wire-drawing mills); Ohio, 5; Connecticut, 4; Wisconsin, 3; Indiana, 4 (including 2 wire-drawing mills); Maryland, 2; and New Hampshire, Rhode Island, and West Virginia, 1 each.

In 1900, 4,603,010 kegs of iron and steel wire nails were reported as the product of 11 establishments which rolled rods and drew wire, as compared with 9,061,512 kegs by 21 establishments in 1905. This is an increase of 90.9 per cent in number of establishments and of 96.9 per cent in quantity of product.

The decline in the cut nail industry, which started in 1886, has continued. In 1900 cut nails were manufactured by 23 rolling mill establishments to the amount of 1,689,143 kegs, whereas in 1905 there were 17 producing establishments, with a product of

1,311,549 kegs, a decrease of 26.1 per cent in number of establishments and 22.4 per cent in output.

Wire.—In 1905 there were 25 rolling mill establishments making wire rods, which drew iron and steel wire, of which establishments 12 manufactured therefrom wire products, principally fencing and netting. The wire, reported as such, amounted to 624,298 short tons, valued at $30,992,672, an average price of $49.64 per short ton, and the wire products to 339,121 short tons, valued at $19,063,409, or $56.21 per short ton. The two combined give an iron and steel wire production, not including wire nails, of 963,419 short tons, valued at $50,056,081. If the weight of the 9,061,512 kegs of wire nails is added thereto, 1,416,495 short tons is obtained as the total quantity of iron and steel wire and wire products of all kinds made by rolling mills. The combined value of these products was $67,551,443.

In 1900 the iron and steel wire product reported by rolling mills and steel works (not including wire nails) was 579,595 gross tons, valued at $35,283,688, or an average value of $60.88 per gross ton, which is equivalent to 649,146 short tons, of an average value of $54.35 per ton.

In addition to the wire products of the rolling mills, iron and steel wire was drawn from purchased wire rods in 1905 by 16 establishments in the industry classified as "wire." The value of the iron and steel wire products of these establishments was $17,362,395, distributed as follows:

Total	$17,362,395
Wire, as such	5,148,731
Barb wire	3,851,136
Wire nails	4,017,830
Field fencing	2,914,802
Poultry netting	505,797
Hay and bale ties	248,277
Other wire products	675,822

There occurs in the above a duplication of $1,559,882 on account of wire purchased, after deducting which $15,802,513 remains as the value of the wire and wire products made by wire drawing mills from purchased wire rods.

The quantity of the wire and wire products produced by wire drawing establishments does not appear, but on the basis of an average value of $50 per ton, approximately that of the rolling mill products, the product of the wire drawing establishments, other than rolling mills, would appear to be approximately 316,000 short tons, which, added to the wire products of the rolling mills, 1,416,494 short tons, gives an approximate total of 1,732,000 short tons of wire products, of a value of $83,353,956, as the output of all establishments.

In addition to the above, wire nails, valued at $2,787,159, were made by establishments in the industry classified as "iron and steel, nails and spikes, cut and wrought, including wire nails, not made in rolling mills or steel works." Some of these nails were made from purchased wire, and some from purchased wire rods drawn by the establishments. As the amount of wire drawn by these establishments can not be determined, it is not included in the above statement.

The following tabular statement shows the production of the wire industry as a whole for 1900 and 1905:

Wire manufactured—comparative summary: 1905 and 1900.

	1905	1900	Per cent of increase.
Aggregate value	$83,353,956	$52,871,387	57.7
Rolling mills:			
Total wire and wire products—			
Short tons	1,416,494	879,296	61.1
Value	$67,551,443	$47,728,784	41.5
Total wire and wire products, not including wire nails—			
Short tons	963,419	649,146	48.4
Value	$50,056,081	$35,283,688	41.9
Iron and steel wire—			
Short tons	624,298	.....	.....
Value	$30,992,672	.....	.....
Iron and steel wire products, not including wire nails—			
Short tons	339,121	.....	.....
Value	$19,063,409	.....	.....
Wire nails—			
Short tons	453,075	230,150	96.9
Value	$17,495,362	$12,445,096	40.6
Establishments in "wire" industry:			
Total iron and steel wire and wire products, made from purchased wire rods	$15,802,513	$5,142,603	207.3

The rolling mills producing wire and wire products in 1905 were distributed as follows: 8 in Pennsylvania, 3 in New Jersey, 2 each in Illinois, Indiana, New York, and Ohio; and 1 each in Alabama, Colorado, Connecticut, Kentucky, Massachusetts, and Rhode Island. Of the establishments otherwise classified which draw iron and steel wire from purchased wire rods in 1905, 4 were in Illinois, 4 in Massachusetts, 3 in Pennsylvania, 2 in Indiana, 2 in New Jersey, and 1 in New York.

The state of Pennsylvania produced 189,121 short tons of wire, valued at $7,847,348, and 149,102 short tons of "other wire products," valued at $6,562,460, or 35.1 per cent of the wire and wire products, not including wire nails manufactured by rolling mills; Ohio, Illinois, and Massachusetts were the next in rank as producers. Nearly 80 per cent of the iron and steel wire and wire products of mills which used purchased wire rods, was from the state of Illinois, and if the wire industry is considered as a whole, without regard to whether mills roll their rods or purchase them, this state easily ranks second.

Bolts, nuts, rivets, forged spikes, washers, etc.—The manufacture of bolts, nuts, rivets, forged spikes, washers, etc., was reported by 30 rolling mill establishments in 1905, to the extent of 277,306 tons, valued at $13,854,635, or at an average value of $49.96 per ton. Products of this class, valued at $14,283,972, were made by 88 establishments other than rolling

mills. On the basis of the average price per ton of the manufactures of the rolling mills ($49.96) an estimate of 285,908 tons is obtained as the quantity of this product. The total quantity for all bolts, nuts, rivets, forged spikes, etc., was on this basis over 560,000 tons.

The rolling mills reporting these products comprised 10 in Pennsylvania, 3 each in Illinois and Virginia, 2 each in California and Ohio, and 1 each in Colorado, Connecticut, Delaware, Indiana, Kentucky, Massachusetts, Missouri, New Jersey, New York, and Wisconsin. Pennsylvania reported more than one-half and Illinois nearly one-fifth of those produced by rolling mills.

Wrought pipe.—The manufacture of wrought pipe or tubes was reported by 14 rolling mill establishments, of which 9 were in Pennsylvania, 2 in Ohio, and 1 each in Illinois, New York, and West Virginia. The production, 849,047 tons, valued at $43,985,728, averaged in value $51.81 per ton. In addition wrought pipe of the value of $15,541,450 was produced by 13 establishments which purchased skelp. These 13 establishments appear in the industry classified as "iron and steel pipe, wrought," the total value of the products of which are $17,400,912, consisting of the wrought pipe product made from purchased skelp, just referred to, and seamless drawn, clinched, brazed, riveted, and other pipe or tubes, valued at $1,859,462. On the basis of the average value per ton of wrought pipe shown by the rolling mill product, the wrought pipe made from purchased skelp by establishments other than rolling mills represents in quantity nearly 300,000 tons, and makes with the rolling mill product a total of approximately 1,150,000 tons, valued at $59,527,178.

Seamless-drawn, clinched, brazed, etc., pipe or tubes.—Eight rolling mill establishments located in Pennsylvania, Ohio, and Michigan reported the manufacture of 20,636 tons of seamless drawn, clinched, brazed, etc., pipe or tubes of a value of $2,290,234, or an average of $110.98 per ton. In the industry classified as "iron and steel pipe, wrought," there were reported by 15 establishments products of a like character aggregating $1,859,462, making a total of $4,149,696.

Horse and mule shoes.—The manufacture of horse and mule shoes was reported by 11 rolling mill establishments and by 8 establishments otherwise classified. Of the former, 2 each were located in New York, Pennsylvania, and Virginia, and 1 each in Delaware, Illinois, New Jersey, Rhode Island, and Wisconsin. The product of the rolling mills aggregated 68,594 tons, valued at $5,483,137, or $79.94 per gross ton. Of the establishments other than rolling mills, which manufacture horse and mule shoes, 3 were located in Pennsylvania, and 1 each in Connecticut, Massachusetts, Minnesota, New Jersey, and New York. The product of the establishments, not rolling mills, is of a value of $798,981; and estimated on the basis of the value reported for the rolling mill horse and mule shoe product, it is equivalent to about 10,000 tons. This combined with the rolling mill product gives a total product of 78,594 tons. The New York rolling mill establishments produced the largest amount of horse and mule shoes, and Pennsylvania ranked second. These 2 states produced more than one-half of the rolling mill product.

Springs.—Car, carriage, furniture, and other springs were made by 9 steel works and rolling mill establishments to the amount of 22,022 tons, valued at $1,708,632, an average value of $77.59 per ton. Of these steel works and rolling mills, 2 each were located in Michigan and Pennsylvania, and 1 each in California, Connecticut, Illinois, Massachusetts, and New Jersey.

The greater part of the iron and steel springs for cars, carriages, etc., was made by establishments otherwise classified. Of the latter, there were 52, reporting products valued at $5,740,836. Less than 23 per cent of this class of products was from establishments which made or rolled their own steel.

The other miscellaneous iron and steel products specifically reported by steel works and rolling mills will be found in Table 45. It is not possible to show the total product of cast iron pipe or gray iron and malleable castings, as the greater part of the same is included in the reports of establishments classified under "foundry and machine shop products," and can not be segregated.

The manufacture of 1,594 tons of ordnance, valued at $988,804, was reported by steel works and rolling mills, and products valued at $557,903 by establishments classified as "ordnance and ordnance stores," making a total value of $1,546,707.

The rolling mill establishments reported stamped ware valued at $292,923, which should be combined with the product of establishments making stamped ware as a specialty. They reported machinery manufactured to the extent of $1,269,675, which is a by-product for "foundry and machine shop products," and shovels, spades, scoops, etc., valued at $410,500, a by-product for "tools, not elsewhere specified."

The manufacture of copper rods was reported by 3 establishments classified as steel works and rolling mills, which were located in Illinois, Massachusetts, and Pennsylvania; and copper wire by 3 establishments located in Illinois, Massachusetts, and New Jersey.

EQUIPMENT.

Table 48 shows the equipment and capacity of the steel works and rolling mills in 1905, as compared with 1900, 1890, and 1880.

TABLE 48.—*Steel works and rolling mills—active and idle establishments—number, equipment, and capacity: 1880 to 1905.*

	1905	1900	1890	1880
Steel works and rolling mills:				
Number of establishments	[1] 518	476	429	391
Total daily capacity, finished, rolled, and forged products, tons, double turn	[1] 115,210	90,122	41,576	19,730

Crucible pots which can be used at a heat	2,939	2,619	2,606	2,691

[1] Exclusive of forges and bloomeries but including 31 establishments other than steel works and rolling mills. (See Table 13.)
[2] Not reported.

This comprises both active and idle establishments and includes those otherwise classified. The number of establishments shows an increase of 42, or 8.8 per cent, and their daily capacity of finished rolled and forged products, an increase of 25,088 tons, or 27.8 per cent. Establishments having Bessemer converters have increased 7 in number and 12 in number of converters, while the open-hearth steel establishments have gained 30 in number and 184 in number of furnaces, 7 of the latter being acid furnaces and 177 basic. Crucible establishments have increased slightly in number and considerably in equipment. Equipment for the production of steel by other or miscellaneous processes was reported by 6 establishments, including 1 establishment otherwise classified. Of the total number of active and idle establishments classified under steel works and rolling mills, 93 were equipped both for the production of steel and for the manufacture of hot rolled iron and steel products; 74, for the production of steel ingots and castings only; and 320, for the production of hot rolled iron and steel products only. There were thus 167 establishments equipped for steel production and 413 for the manufacture of hot rolled iron and steel products.

Of the total number of establishments in 1900, 42 were equipped for the manufacture of Bessemer steel, with 91 converters; 96, for the manufacture of open-hearth steel, with 331 furnaces; 40, for the manufacture of crucible steel, with 2,619 pots; and 11, for the manufacture of steel by miscellaneous processes. There were in 1900, 425 establishments equipped for the manufacture of hot rolled iron and steel products, while 51 were not so equipped. In 1890, 299 produced rolled iron and steel, but not steel ingots or castings, and 130 were equipped for the production of steel.

STEEL PRODUCTION.

The following tables present, by states, the production of steel ingots and direct steel castings reported at the census of 1905 and former census years.

Table 49 shows the total production of all kinds of steel ingots and castings, by states, 1880 to 1905.

TABLE 49.—STEEL WORKS—QUANTITY OF STEEL INGOTS AND DIRECT STEEL CASTINGS, BY STATES: 1880 TO 1905.

[1] Includes 4,184 tons of steel castings made by establishments engaged primarily in the manufacture of other products.
[2] California produced a small quantity of Tropenas steel castings in 1900, which was included in the statistics for the iron and steel shipbuilding industry.
[3] Connecticut produced a small quantity of Tropenas steel castings in 1900, but this production is not included in the figures given for this state.

Wisconsin	5,934	857			1,633	790						

The growth of steel production has been the heaviest of any portion of the iron and steel industry. The increase in the steel production in 1905 was 2,985,592 tons over that of 1900, or 27.9 per cent. This is an average increase of nearly 600,000 tons per year. The product for 1900 shows a gain over that of 1890 of 6,510,348 tons, or 155.9 per cent, an average increase of about 650,000 tons per year; and the product of 1890 shows a gain over that of 1880 of 3,147,271 tons, or 306.3 per cent, an average increase of nearly 315,000 tons per year.

The following tabular statement shows the proportion of the total that Bessemer steel, open-hearth steel, and crucible and miscellaneous steels, respectively, formed for the several census years:

KIND.	PER CENT OF TOTAL STEEL PRODUCTION.			
	1905	1900	1890	1880
Total	100.0	100.0	100.0	100.0
Bessemer steel	56.8	70.5	86.6	85.6
Open-hearth steel	42.6	28.5	11.5	7.3
Acid	5.5	8.3		
Basic	37.1	20.2		
Crucible and miscellaneous steel	0.6	1.0	1.9	7.1

When compared with other branches of the iron and steel industry, the growth is particularly noticeable. The increase in the steel tonnage for the last five years, as above noted, was 27.9 per cent; whereas the increase in the tonnage of pig iron was 15.1 per cent, and of all rolling mill products, 21.1 per cent.

The increase in Bessemer steel since 1900 has been relatively small—236,887 tons, or 3.1 per cent; whereas open-hearth steel has increased 2,776,041 tons, or 91.2 per cent. For the decade from 1890 to 1900, Bessemer steel increased 3,914,830 tons, or 108.2 per cent, and open-hearth steel, 2,564,321 tons, or 534.2 per cent; whereas for the decade from 1880 to 1890, Bessemer steel increased 2,737,548 tons, or 311.2 per cent, and open-hearth steel, 404,766 tons, or 537.8 per cent. Crucible and miscellaneous steels show a slight decrease.

Pennsylvania contributed 56.6 per cent of the total steel product in 1905, 60.2 per cent in 1900, 63.5 per cent in 1890, and 57.1 per cent in 1880. Ohio made 18.5 per cent in 1905, 17 per cent in 1900, 9.5 per cent in 1890, and 9.4 per cent in 1880. Illinois, ranking third in the production of steel, made 11.4 per cent in 1905, 13.7 per cent in 1900, 18.7 per cent in 1890, and 22.1 per cent in 1880. These 3 states combined produced 86.5 per cent of the total in 1905, 90.8 per cent in 1900, 91.7 per cent in 1890, and 88.6 per cent in 1880. A large increase appears in a number of the other states, notably in Alabama and New York. Delaware, Rhode Island, and Oregon appear as steel producers for the first time in 1905.

Table 50 shows the daily capacity of all steel plants, active and idle, on double turn, together with the production of steel ingots and castings, by states, for 1905.

TABLE 50.—STEEL WORKS—CAPACITY OF PLANTS AND QUANTITY AND VALUE OF STEEL INGOTS AND CASTINGS, BY STATES: 1905.

[1] Includes 4,184 tons of steel castings, valued at $347,264, made by establishments engaged primarily in the manufacture of other products.

Computed from the daily capacity, on a basis of three hundred working days for the year, the total yearly capacity of the active establishments is about 23,500,000 tons. The production was thus approximately 58 per cent of the capacity of the active establishments. In 1900 it was estimated as 66.3 per cent of the total capacity of active establishments. Steel ingots constituted 97.9 per cent of the production and castings 2.1 per cent. In 1900 ingots formed 98.3 per cent and castings 1.7 per cent of the steel production. The average value per ton of all ingots and castings was $19.11 in 1905 and $19.89 in 1900.

Table 51 presents, for 1905, the statistics of the production of steel ingots, by states, certain states being grouped, as in the other tables, to avoid disclosing individual operations.

TABLE 51.—STEEL WORKS—QUANTITY AND VALUE OF STEEL INGOTS, BY KIND AND STATES: 1905.

Of the total ingot production, 58 per cent was Bessemer, 41.5 per cent open-hearth, and six-tenths of 1 per cent crucible; whereas in 1900, 71.6 per cent was Bessemer, 27.4 per cent open-hearth, and 1 per cent crucible. The average value for all ingots was $17.96 per ton; for Bessemer ingots, $17.15 per ton; for open-hearth ingots, $18.34 per ton; and for crucible steel ingots, $73.10 per ton. In 1900 the average values were—for all ingots, $18.84 per ton; for Bessemer, $17.51; for open-hearth, $20.44; and for crucible steel, $72.33.

Table 52 presents, for 1905, the statistics relating to direct steel castings. Those made by miscellaneous steel furnaces, amounting to 431 tons, are combined with the crucible steel castings.

TABLE 52.—STEEL WORKS—QUANTITY AND VALUE OF STEEL CASTINGS, BY KIND AND STATES: 1905.

[1] Includes 4,184 tons of steel castings, valued at $347,264, made by establishments engaged primarily in the manufacture of other products.

Of the total amount, 93.3 per cent was made of open-hearth steel, 4.9 per cent of Bessemer, and 1.7 per cent of crucible and miscellaneous steel. In 1900, 93.4 per cent was open-hearth, 2.1 per cent Bessemer, and 4.4 per cent crucible and miscellaneous. The average value per ton of all castings was $71.86; of Bessemer castings, $117.19; of open-hearth castings, $68.90; and of those made of crucible and miscellaneous steels, $101.74. The value of direct steel castings reported shows a wide range—from $26 per ton in certain sections to $175 per ton in others. In 1900 the average value per ton of all castings was $82.47; of Bessemer castings, $85.74; of open-hearth castings, $78.56; and of crucible and miscellaneous steels, $163.09.

Bessemer steel.—The production of Bessemer steel ingots and castings, and the equipment of all establishments, active and idle, for such production, is shown, for 1905, in Table 53.

[1] Including 8 establishments other than steel works. (See Table 13.)
[2] Includes 774 tons of steel castings, valued at $92,685, made by establishments engaged primarily in the manufacture of other products.

The above table does not include 2 converters of the Tropenas type in Government establishments. It does, however, include the Bessemer equipment of the establishments otherwise classified (see Table 13).

Table 54 shows, for 1905, the equipment of all Bessemer steel works with the types of converters and the daily capacity, by states.

[1] Includes 8 establishments other than steel works (see Table 13) and 2 Government institutions (District of Columbia and Massachusetts) having 2 Tropenas converters.
[2] Bookwalter.
[3] Clapp-Griffiths.
[4] Robert-Bessemer.
[5] Two Evans-Willis converters of 16 tons daily capacity, 3 top-blown converters of 9 tons daily capacity, and 1 special converter of 20 tons daily capacity.
[6] Top-blown.
[7] Special.

In 1880 the usual capacity of the standard Bessemer converter was 5 tons, and in 1890 converters of 10 to 12 tons were in use. In 1900 the capacity of a number of converters had further increased to 15 tons, and at one establishment 20-ton converters had been installed. This capacity has not been exceeded.

Nineteen states report plants equipped with converters. The total production of steel ingots and castings in 1905 amounted to 7,768,915 tons, valued at $134,642,265, as compared with 7,532,028 tons in 1900, of a value of $132,113,984, an increase of 3.1 per cent in tonnage and of 1.9 per cent in value. The ingot product of 1905 amounted to 7,754,488 tons, of a value of $132,951,636, an average value of $17.15, compared with 7,528,267 tons in 1900, valued at $131,791,519, or $17.51 per ton. The castings amounted in 1905 to 14,427 tons, of a value of $1,690,629, an average value of $117.19 per ton, as compared with 3,761 tons in 1900, valued at $322,465, or $85.74 per ton. This is an increase for ingots of 3 per cent in tonnage and for castings, of 283.6 per cent. Pennsylvania produced 44.3 per cent of the total products of Bessemer ingots and castings in 1905, compared with 51.9 per cent in 1900; and Ohio, 26.4 per cent, compared with 22.5 per cent.

The states of Pennsylvania, Ohio, Illinois, and New York produced 90.8 per cent of all Bessemer steel ingots and castings in 1905; no other state produced over 4 per cent. Over 60 per cent of the Bessemer steel castings was produced by the state of New York. The next states in rank were New Jersey, Michigan, Wisconsin, Alabama, Delaware, and Illinois, in the order named. No other state produced over 400 tons of direct Bessemer steel castings.

Included in the foregoing is the product of all converters, whether of the standard Bessemer or other type. The product of the Tropenas and of converters other than standard Bessemer amounted to 11,834 tons of castings, of a value of $1,596,476, making an average value of $134.90 per ton. The tonnage and value of castings made by the establishments before referred to as otherwise classified are not of course included unless these were sold as products.

Of the Bessemer steel castings made by other than standard Bessemer converters, New Jersey produced 35.6 per cent; Michigan, 21.5 per cent; New York, 14.5 per cent; and Wisconsin, 14 per cent. No other state produced over 7.4 per cent.

Open-hearth steel.—The production and value of all open-hearth steel ingots and castings, acid and basic, is shown, for 1905, in Table 55, by states, together with the number of establishments, both active and idle, equipped with open-hearth furnaces.

TABLE 55.—OPEN-HEARTH STEEL WORKS—NUMBER OF ESTABLISHMENTS AND FURNACES, AND QUANTITY AND VALUE OF STEEL PRODUCED, BY STATES: 1905.

[1] Includes 2,440 tons of steel castings, valued at $179,575, made by establishments engaged primarily in the manufacture of other products.

The production of open-hearth steel ingots and castings in 1905 was 5,820,397 tons, as compared with 3,044,356 tons in 1900, 480,035 tons in 1890, and 75,269 tons in 1880. This shows an increase of 91.2 per cent for the five-year period from 1900 to 1905, compared with 534.2 per cent for the decade ending 1900, and 537.8 for that ending in 1890.

In 1900 there were 96 establishments equipped with 331 open-hearth furnaces, of which 82 establishments, having 307 furnaces, were active, and 14 establishments, with 24 furnaces, were idle. In 1905, 126 establishments report 515 open-hearth furnaces, an increase of over 30 per cent in number of establishments, and of 55.6 per cent in number of furnaces. In 1880 the open-hearth furnaces ranged from 7 to 10 tons capacity per heat; in 1890 many furnaces handled from 20 to 30 tons; and in 1900 a large number of furnaces of 50-ton capacity were in use. In 1905 there were reported 6 open-hearth furnaces of a capacity of 60 tons at a heat, and 169 of a capacity of 50 tons.

The 489 active furnaces in 1905 show an average product for the year of 11,903 tons per furnace, whereas in 1900 the 307 active furnaces had an average product of 9,916 tons per furnace for the year.

In 1905, 87 per cent of the open-hearth steel was made in basic furnaces and 13 per cent in acid, compared with a production in 1900 of 70.7 per cent basic steel and 29.3 per cent acid steel. In fact, the production of acid open-hearth steel declined from 890,521 tons in 1900 to 755,805 tons in 1905, or a decrease of 15.1 per cent, and basic open-hearth steel advanced from 2,153,835 tons in 1900 to 5,064,592 tons in 1905, an increase of 135.1 per cent.

The average value per ton of all open-hearth steel made in 1905 was $20.70, acid steel being $34.31 per ton, and basic $18.67 per ton. In 1900 the average value of all open-hearth steel was $23.60 per ton; of acid steel, $31.83 per ton; and of basic, $20.20 per ton.

Acid open-hearth steel was made in 11 states. Pennsylvania produced 78.3 per cent of the total product, compared with 77.6 per cent in 1900; Ohio, 7.4 per cent, compared with 5.9 per cent in 1900; Illinois, 3.1 per cent, compared with 3.9 per cent in 1900.

Basic open-hearth steel was made in 13 states in 1905. Pennsylvania produced 71.9 per cent, as compared with 81.1 per cent of the total production in 1900; Ohio, 8.4 per cent, compared with 2.9 per cent in 1900; and Illinois, 6.7 per cent, compared with 10 per cent in 1900.

Acid steel only was produced by 46 active open-hearth establishments, basic steel only by 40 establishments, and both acid and basic steel by 19 establishments. In the case of 5 active establishments having open-hearth furnaces, no open-hearth steel was reported. In 1900, 36 of the active establishments produced acid steel only; 19, basic steel; and 17, both acid and basic. In 1905, 46 of the open-hearth establishments produced ingots only; 44, castings only; and 15, both ingots and castings. In 1900, 38 establishments made ingots alone; 32, castings alone; and 12, both ingots and castings.

Table 56 presents in detail, for 1905, by states or groups of states, the production and value of acid and basic steel ingots and castings.

Ohio	12	425,007	8,439,556	399,922	6,684,963	25,085	1,754,593
Pennsylvania	51	3,638,986	64,097,810	3,628,715	63,732,224	10,271	365,586

[1] Includes 2,440 tons of steel castings, valued at $179,575, made by establishments engaged primarily in the manufacture of other products.

Of the total open-hearth steel production, 95.3 per cent was ingots and 4.7 per cent castings; 87 per cent was made in basic furnaces and 13 per cent in acid. Of the ingots, 89.7 per cent were basic and 10.3 per cent acid; while of the castings, 67 per cent were of acid steel and 33 per cent basic.

The average value of the ingots was $18.34 per ton; of the basic ingots, $17.85 per ton; and of the acid, $22.61 per ton. The average value of the castings was $68.90 per ton; of the acid castings, $71.10 per ton; and of the basic, $64.41 per ton. Pennsylvania made 72.7 per cent of all open-hearth steel, and the average value of its contribution was $19.62 per ton; 74.2 per cent of all ingots, their average value being $18.25 per ton; 72.9 per cent of the basic ingots, at $17.56 per ton; 85.2 per cent of the acid ingots, at $23.31 per ton; and 41.7 per cent of all castings, at $69.54 per ton—56.6 per cent of the acid at $72.92 per ton, and 11.5 per cent of the basic at $35.59 per ton.

Ohio was second in the production of all open-hearth steel, making 8.3 per cent, at $20.52 per ton; second in the production of ingots, making 8 per cent, at $16.65 per ton; 8 per cent of the basic ingots, at $16.72 per ton; and 7.6 per cent of the acid ingots, at $16.05 per ton; and third in castings, making 13.8 per cent, at $66.17 per ton.

Illinois was third in all open-hearth steel, making 6.2 per cent, at $27.15 per ton; third in ingots, making 5.5 per cent, nearly all basic ingots (and 6.2 per cent of the total basic), at $18.58 per ton; and second in castings, making 20.3 per cent, at $74.63 per ton.

Alabama was fourth in all open-hearth steel production, making 3.9 per cent, at $19.66 per ton; fourth in the production of ingots, its output constituting 4.1

per cent of all ingots and 4.5 per cent of all basic ingots, at $19.61 per ton; it produced also a relatively small amount of basic castings.

These 4 states—Pennsylvania, Ohio, Illinois, and Alabama—made 5,299,873 tons of open-hearth steel, or 91.1 per cent of the total amount; 5,092,947 tons of ingots, or 91.8 per cent of the total; and 206,926 tons of castings, or 76.1 per cent of the total.

There were 54 establishments which made open-hearth steel castings in 1905, 35 made acid castings only, 12 basic castings only, and 7 made both acid and basic. The establishments which made steel castings only and no steel ingots were equipped with 56 acid open-hearth furnaces and with 31 basic furnaces. Of the 44 establishments which made open-hearth castings in 1900, 39 made acid castings only, 4 basic castings only, and 1 both acid and basic. The establishments which produced steel castings only in 1900 were equipped with 51 acid and 9 basic furnaces.

The average value per ton of all open-hearth steel castings was $68.90 in 1905 and $78.56 in 1900. Acid castings had an average value of $71.10 per ton in 1905, and basic an average value of $64.41. Pennsylvania produced 41.7 per cent of the total output in 1905, of an average value of $69.54 per ton, as compared with 41.2 per cent of the total output, of an average value of $81.43, in 1900. Pennsylvania made 56.6 per cent of the acid castings, of an average value of $72.92 per ton in 1905, and 50.2 per cent, of a value of $83.27, in 1900.

Illinois ranked second in the manufacture of all steel castings, Ohio third, and New York fourth. In output of acid castings, Illinois was second, New York third, and Ohio fourth; and of basic, Illinois was first, Ohio second, New York third, and Pennsylvania fourth. In 1900 basic steel castings were made in only 3 states—Illinois, Missouri, and Pennsylvania; in 1905 they are reported by 7 states—the 3 mentioned above and Alabama, Colorado, New York, and Ohio.

Table 57 shows the number and capacity of the open-hearth furnaces, acid and basic, in active and idle establishments, including those "otherwise classified" (see Table 13), by states. In order to show the heavy increase in the basic open-hearth furnace equipment since the Twelfth Census, the statistics are presented for both 1900 and 1905.

TABLE 57.—OPEN-HEARTH STEEL WORKS—NUMBER AND DAILY CAPACITY OF ACID AND BASIC FURNACES, BY STATES: 1905 AND 1900.

The number of establishments having open-hearth furnace equipment increased 31.3 per cent, the number of furnaces 55.6 per cent, and the furnace capacity 86.3 per cent. The growth has been chiefly in the basic furnaces, which increased in number 98.9 per cent and in capacity 119.7 per cent. In 1905 the average daily capacity per furnace (double turn) for all furnaces was 68.8 tons; for acid furnaces, 48.7 tons; and for basic furnaces, 77.8 tons; compared with corresponding figures for 1900 of 57.5 tons, 42.2 tons, and 70.5 tons, respectively. The basic furnaces in 1905 constituted 69.1 per cent of the total number and 78.1 per cent of the total capacity; in 1900 they formed 54.1 per cent of the total number and 66.3 per cent of the total capacity.

Crucible and miscellaneous steels.—Table 58 shows the equipment, capacity, and production of the crucible steel works, by states, for 1905. Some of the states are grouped, in order not to disclose individual operations.

TABLE 58.—CRUCIBLE STEEL WORKS—NUMBER, EQUIPMENT, AND CAPACITY OF ESTABLISHMENTS, AND QUANTITY AND VALUE OF INGOTS AND CASTINGS, BY STATES: 1905.

[1] Includes 6 establishments other than steel works. (See Table 13.)
[2] Includes 180 tons of steel castings, valued at $18,004, made by establishments engaged primarily in the manufacture of other products.

In 1880 the production of crucible steel amounted to 68,037 tons; in 1890, to 73,882 tons; in 1900, to 104,393 tons; and in 1905, to 80,059 tons. In 1880 there were 37 establishments, located in 9 states; in 1890, 47, located in 11 states; in 1900, 40, located in 10 states; and in 1905, 49, located in 10 states.

In 1905 the average value per ton of all crucible steel was $74.43. Of the total amount, 95.2 per cent were ingots of an average value of $73.10 per ton, and 4.8 per cent castings of an average value of $100.54 per ton. For 1900 the average value of all crucible steel was $74.46 per ton; of ingots, $72.33 per ton; and castings, $133.53. In 1900 ingots constituted 96.5 per cent and castings 3.5 per cent of all crucible steel.

Pennsylvania made about three-fourths of all crucible steel, and New Jersey, New York, and Massachusetts were next, in the order named. Wisconsin was the largest producer of crucible steel castings.

In 1900 there was reported a total of 2,619 pots that could be used at a heat, with a daily capacity of 525.5 tons.

The production of steel by other or miscellaneous processes is comparatively small. In 1880 there was reported 4,425 tons by miscellaneous processes from Connecticut, New Jersey, and Pennsylvania; in 1890, 3,537 tons from New Jersey and Pennsylvania; and in 1900, 4,223 tons from New Jersey and Pennsylvania. In 1905 steel made by miscellaneous processes was reported for Pennsylvania to the amount of 431 tons.

FORGES AND BLOOMERIES.

The statistics of the few remaining forges and bloomeries which manufacture for sale hammered charcoal blooms, billets, and bars direct from iron ore and hammered charcoal blooms, billets, and bars from pig iron and from scrap iron and steel, have been included for 1905 in those for steel works and rolling mills, but are here presented in detached form for comparison with former years. Establishments which consume in their own works the charcoal blooms or bars are not included.

Table 59 shows the leading statistics for forges and bloomeries for the census years 1870 to 1905.

TABLE 59.—*Forges and bloomeries—comparative summary: 1870 to 1905.*

	1905	1900	1890	1880	1870[1]
Number of establishments	6	7	20	93	82
Capital	[2] $222,112	[2] $508,388	$876,470	$3,915,213	$4,506,733

Salaries	$4,935	$11,500	[3] $17,309	(4)	(4)
Wage-earners, average number	68	226	471	2,939	2,902
Total wages	$33,355	$97,184	$199,065	$915,395	$195,964
Men 16 years and over	68	226	468	2,875	2,819
Wages	$33,355	$97,184	$198,705	(4)	(4)
Women 16 years and over				3	2
Wages				(4)	(4)
Children under 16 years			3	61	81
Wages			$360	(4)	(4)
Miscellaneous expenses	$14,049	$15,203	$54,680	(5)	(5)
Cost of materials used	$100,233	$327,160	$905,208	$2,546,915	$5,685,466
Value of products [6]	$158,612	$522,432	$1,183,494	$3,968,074	$7,647,054
Tons of products	5,626	15,497	31,049	64,783	98,936

[1] Includes idle establishments which were not reported separately in 1870.
[2] Includes value of rented property—1905, $9,500; 1900, $236,000. No rented property reported for previous censuses.
[3] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Not reported.
[6] Includes value of miscellaneous products for which tonnage was not reported.

In 1880 there were 93 active establishments manufacturing hammered blooms, bars, etc., located in Missouri, New Jersey, New York, Pennsylvania, Georgia, North Carolina, Tennessee, and Virginia. In 1890 the number had declined to 20, located in New York, Pennsylvania, Maryland, and New Jersey; and in 1900 was further reduced to 7, located in New York, Pennsylvania, and Maryland. In 1905 there were only 6 active establishments, of which 5 were located in Pennsylvania and 1 in Maryland.

Since 1900 a decrease is shown of $286,276, or 56.3 per cent, in capital invested; of 69.9 per cent in number of wage-earners employed; of 69.3 per cent in the cost of materials; of 69.6 per cent in the value of products; and of 63.7 per cent in the tonnage.

The capital invested in active and idle forges and bloomeries in 1905, 1900, 1890, and 1880 is shown in Table 60.

TABLE 60.—*Forges and bloomeries—active and idle establishments—capital: 1880 to 1905.*

	Census.	Number of establishments.	CAPITAL. Total.	Buildings, machinery, tools, and implements.	Land, cash, and sundries.
Total	1905	7	[1] $256,639	$70,681	$185,958
	1900	14	[1] 619,488	236,420	383,068
	1890	32	1,074,970	462,500	612,470
	1880	118	4,395,963	2,301,550	2,094,413
Active	1905	6	222,112	37,154	184,958
	1900	7	508,388	184,420	323,968
	1890	20	876,470	338,000	538,470
	1880	93	3,915,213	2,018,800	1,896,413
Idle	1905	1	34,527	33,527	1,000
	1900	7	111,100	52,000	59,100
	1890	12	198,500	124,500	74,000
	1880	25	480,750	282,750	198,000

[1] Includes value of rented property—1905, $9,500; 1900, $236,000. No rented property reported for previous censuses.

The idle establishment in 1905 was in the state of New York. The materials and quantities and cost are shown in detail for 1880, 1890, 1900, and 1905 in Table 61.

TABLE 61.—FORGES AND BLOOMERIES—MATERIALS USED, BY KIND, QUANTITY, AND COST: 1880 TO 1905.

[1] Bushels. [2] Short tons.

Table 62 shows the quantity and value of the products for 1880, 1890, 1900, and 1905. In 1880 and 1890 the cost of materials reported included all freight charges, whereas in 1900 and 1905 this was not always the case. Where freight is not included in the cost of materials it has been added to "all other materials."

The 1905 product was all blooms, billets, etc., nearly all of which were made from scrap iron and steel.

The blooms, billets, etc., had an average value of $28 per ton in 1905, compared with $32.63 per ton in 1900, $36.17 in 1890, and $68.31 in 1880.

TABLE 62.—FORGES AND BLOOMERIES—PRODUCTS, BY KIND, QUANTITY, AND VALUE: 1880 TO 1905.

[1] The figures for the various items in this table do not agree with the corresponding figures for 1905 in all other tables, because the figures for a blast furnace in Texas, operated by a penal institution, have been excluded. This institution reported $255,382 invested as capital; 5 salaried employees who were paid $7,020; 100 wage-earners who received $13,400; miscellaneous expenses, $3,000; materials costing $25,531; and 4,609 tons of charcoal pig iron, valued at $66,419, as products. The furnace has a daily capacity of 50 tons.

151	Daily capacity, tons	1,035				

[1] The figures for the various items in this table do not agree with the corresponding figures for 1905 in all other tables, because the figures for a blast furnace in Texas, operated by a penal institution, have been excluded. This institution reported $255,382 invested as capital; 5 salaried employees who were paid $7,020; 100 wage-earners who received $13,400; miscellaneous expenses, $3,000; materials costing $25,531; and 4,669 tons of charcoal pig iron, valued at $66,419, as products. The furnace has a daily capacity of 50 tons.

	Scrap iron and scrap steel (cast or wrought)—								
	Used in standard or modified Bessemer converters—								
82	Tons	534,916	.....	.....	.....	.....	99,418	.....	.....
83	Cost	$6,290,542	.....	.....	.....	.....	$1,081,684	.....	.....
	Used in acid open-hearth steel furnaces—								
84	Tons	562,963	.....	564	655	.....	18,041	2,941	.....
85	Cost	$8,617,039	.....	$4,235	$23,820	.....	$340,586	$34,218	.....
	Used in basic open-hearth steel furnaces—								
86	Tons	2,410,330	7,274	.....	25,368	.....	217,147	43,346	.....
87	Cost	$30,716,565	$93,651	.....	$298,099	.....	$2,530,365	$458,802	.....
	Purchased hammered iron-ore blooms, pig or scrap blooms, and imported Swedish billets and bars—								
88	Tons	81,969	29	.....	.....	25	.....	48,291	3,000
89	Cost	$1,781,126	$581	.....	.....	$750	.....	$854,786	$60,000
	Purchased muck or scrap bar—								
90	Tons	205,951	.....	.....	500	.....	443	6,347	.....
91	Cost	$5,066,732	.....	.....	$17,500	.....	$10,137	$138,922	.....
	Purchased iron or steel skelp—								
92	Tons	259,643	.....	.....	.....	.....	.....	.....	.....
93	Cost	$7,331,935	.....	.....	.....	.....	.....	.....	.....
	Purchased iron or steel ingots, blooms, billets, tin-plate bars, sheet bars, or slabs, except imported Swedish billets and bars—								
94	Tons	4,632,257	51,150	10,000	29,734	12,641	220,129	132,229	28,123
95	Cost	$103,420,970	$1,027,711	$257,513	$732,367	$306,578	$5,332,908	$3,180,469	$968,113
	Purchased wire rods—								
96	Tons	161,914	.....	.....	.....	.....	6,312	357	14,834
97	Cost	$4,774,383	.....	.....	.....	.....	$195,672	$11,067	$396,892
	All other iron or steel—								
98	Tons	105,662	.....	.....	.....	.....	23,878	5,146	.....
99	Cost	$4,377,163	.....	.....	.....	.....	$933,909	$159,364	.....

TIN AND TERNE PLATE

TIN AND TERNE PLATE.

By Story B. Ladd.

A full history of the tin and terne plate industry both abroad and in this country, with an account of the process of manufacture, appeared in the report on the industry for the Twelfth Census. Prior to 1890 the production of tin and terne plate in the United States was of slight importance. Since that date the industry has grown rapidly, as is shown by the increase in production from about 2,236,000 pounds of tin and terne plates in 1891 to over 849,000,000 pounds in 1900 and to over 1,000,000,000 pounds in 1905. As the statistics relating to the manufacture of tin and terne plate as a separate industry were first collected at the census of 1900, comparisons can only be made between 1900 and 1905.

The manufacture of black plates and the subsequent dipping of the plates to coat them with tin or terne metal are, as a rule, accomplished in one and the same establishment, without, in many cases, any distinction being made between labor and expense chargeable to the manufacture of the black plates and that pertaining to the tin and terne dipping. The industry should be treated as an entirety, but for comparative purposes it is desirable to follow the plan of presentation employed at the Twelfth Census. Moreover, as the manufacture of black plates is a rolling mill operation, it is important that the statistics relating thereto be included in those for the industry classified as "steel works and rolling mills." Therefore separate reports were requested for the black plate manufacture and for the tin and terne dipping industry. Where these reports could not be made from book accounts, an apportionment of capital, labor, and expense was accepted, the rolling mill report being credited with the black plate product at the market values and the tin and terne plate dipping report being charged with the same as material used.

In the case of rolling mills making other products than black plates it is impossible to segregate the capital, wage-earners, wages, cost of materials, etc., chargeable to the production of black plates from that pertaining to other products, and hence the statistics include all labor and expense items of such establishments, as well as the value of all products.

THE COMBINED INDUSTRY—TIN AND TERNE DIPPING AND BLACK PLATE.

Table 1 is a comparative summary of the general statistics of the active establishments engaged in the tin and terne dipping and black plate industries for the census years 1900 and 1905.

TABLE 1.—COMBINED INDUSTRY—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1905 AND 1900.

Miscellaneous expenses	$1,815,288	$389,873	$1,425,415	$505,128	$236,456	$268,672	259.4	64.9	430.5
Cost of materials used	[4] $49,016,487	$31,375,714	$17,640,773	[4] $45,004,716	$26,728,150	$18,276,566	8.9	17.4	[2] 3.5
Value of products	[4] $65,679,117	$35,283,360	$30,395,757	[4] $61,912,619	$31,892,011	$30,020,608	6.1	10.6	1.2

[1] Includes 27 establishments in 1905 and 35 in 1900 which manufactured black plates as well as tin and terne plates; 9 in 1905 and 22 in 1900 which manufactured tin and terne plates only; and 8 in 1905 and 9 in 1900 which manufactured black plates only.

[2] Decrease.

[3] Includes value of rented property—1905, $473,000; 1900, $165,000.

[4] Includes a duplication of $22,988,237 in 1905 and $20,590,566 in 1900, the value of black plates reported among the products of the black plate industry and used as material in the tin and terne dipping industry.

As a rule, black plate mills operated in conjunction with dipping establishments produce black plates only, and, with the exception of three cases, black plates constitute the chief product of the independent rolling mills making black plates.

The industry is first considered as a whole, followed by the statistics for the tin and terne dipping industry, and then by those pertaining to the manufacture of black plates. Statistics for the last are included in those for steel works and rolling mills in the report on iron and steel.

The period covered by this report is the calendar year 1904, or the business year of the establishments reporting which most nearly conforms to that year. In the census of 1900 the period covered was from June 1, 1899, to May 31, 1900. The gross ton of 2,240 pounds is used except where otherwise stated.

The establishments which manufacture black plates and also coat them are counted both in the tin and terne dipping industry and in the black plate industry, but such establishments count but one in the number of establishments for the combined industries. There were 27 such establishments in 1905 and 35 in 1900. In other words, 75 per cent of the active dipping establishments were equipped for the manufacture of black plates in 1905, as compared with 61.4 per cent in 1900.

The capital invested in the black plate industry in 1905 constituted 66.4 per cent of the total capital for the combined industries, as against 75.3 per cent in 1900. The cost of materials used as well as the value of the products include a duplication, much of the black plate product of the black plate industry being consumed as material in the tin and terne dipping industry. Thus the cost of the black plates consumed by the dipping establishments was $22,988,237 in 1905 and $20,590,566 in 1900, which leaves $26,021,949 as the approximate cost of materials used by the combined industries in 1905, as against $24,414,150 in 1900. In like manner, deducting the same duplication from the value of products, the approximate value of the products in 1905 was $42,690,880, as compared with $41,322,053 in 1900. This shows an increase of 6.6 per cent in the approximate net cost of materials and 3.3 per cent in the approximate net value of products in 1905, as compared with 1900.

Table 2 shows the capital invested in all establishments, both active and idle, and its distribution between tin and terne dipping establishments and black plate establishments in 1905 and 1900. As the statistics for establishments under construction were not collected at the census of 1905, the statistics for such establishments have been eliminated from the figures for 1900.

TABLE 2.—*Combined industry—active and idle establishments—capital, by industries: 1905 and 1900.*

INDUSTRY.	Census.	Number of establishments.	CAPITAL. Total.	Land.	Buildings, machinery, tools, and implements.	Cash and sundries.
Total....	1905	[1] 54	[2] $33,759,901	$1,676,980	$18,231,751	$13,851,170
	1900	[1] 68	[2] 27,515,527	1,906,125	15,097,265	10,512,137
Tin and terne.	1905	[3] 41	11,339,049	403,100	5,189,297	5,746,652
	1900	59	6,817,272	539,125	2,650,540	3,627,607
Black plate....	1905	41	22,420,852	1,273,880	13,042,454	8,104,518
	1900	44	20,698,255	1,367,000	12,446,725	6,884,530

[1] Includes establishments equipped as follows: 1905—28 plants for the manufacture of black plates and tin and terne plates, 13 plants for the manufacture of tin and terne plates only, and 13 plants for the manufacture of black plates only. 1900—35 plants for the manufacture of black plates and tin and terne plates, 24 plants for the manufacture of tin and terne plates only, and 9 plants for the manufacture of black plates only.

[2] Includes value of rented property—1905, $473,000; 1900, $165,000.

[3] Not including 8 establishments, 6 of which are idle and attached to rolling mills, and 2 to establishments classified as "tinware;" capital not reported separately.

The total capital shows an increase of 22.7 per cent for the period 1900 to 1905, the major part of this increase being in the tin and terne plate dipping industry, in which the capital invested increased 66.3 per cent, while the capital in the black plate industry increased but 8.3 per cent. Of the total capital, that portion invested in buildings, machinery, tools, and implements increased 20.8 per cent and that in cash and sundries, 31.8 per cent. The capital invested in land shows a decrease of 12 per cent, due probably to concentration of the industry during the period.

In 1905, 54 per cent of the total capital was in buildings, machinery, tools, and implements, as against 54.9 per cent in 1900; in the tin and terne plate industry 45.8 per cent was in buildings, machinery, tools, and implements in 1905, as against 38.9 per cent in 1900; and in the black plate industry, 58.2 per cent in 1905, as against 60.1 per cent in 1900.

Table 3 shows the combined capital by active and idle establishments in 1900 and 1905.

TABLE 3.—*Combined industry—active and idle establishments—capital: 1905 and 1900.*

	Census.	Number of establishments.	CAPITAL. Total.	Land.	Buildings, machinery, tools, and implements.	Cash and sundries.
Total..	1905	[1] 54	[2] $33,759,901	$1,676,980	$18,231,751	$13,851,170
	1900	68	[2] 27,515,527	1,906,125	15,097,265	10,512,137
Active.....	1905	44	32,457,487	1,611,380	17,049,327	13,796,780
	1900	66	27,488,302	1,895,400	15,080,765	10,512,137
Idle.....	1905	10	1,302,414	65,600	1,182,424	54,390
	1900	2	27,225	10,725	16,500	.....

[1] Not including 8 tin and terne dipping establishments, 6 of which are idle and attached to rolling mills, and 2 to establishments classified as "tinware;" capital not reported separately.

[2] Includes value of rented property—1905, $473,000; 1900, $165,000.

Of the total amount of capital invested, less than one-tenth of 1 per cent in 1900 was in idle establishments, and in 1905 only 3.9 per cent.

Table 4 shows the capital invested, number of salaried employees and salaries paid, and the average number of wage-earners and total wages paid for the combined industries for the state of Pennsylvania and "all other states" in 1900 and 1905. On account of the control of many tin and terne dipping plants in Indiana, Ohio, and West Virginia by one company, although there are three or more plants in each of these states, the detailed statistics can not be shown separately for the combined industry, or for the tin and terne dipping industry, without disclosing the operations of individual concerns.

TABLE 4.—COMBINED INDUSTRY—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.	
				Number.	Salaries.	Average number.	Wages.
United States	1905	44	[1] $32,457,487	861	$936,662	17,164	$10,559,723
	1900	66	[1] 27,488,302	726	818,015	14,826	10,288,061
Pennsylvania	1905	19	14,942,692	546	592,466	8,511	5,249,701
	1900	30	12,517,557	342	358,566	6,017	4,349,327
All other states	[2] 1905	25	17,514,795	315	344,216	8,653	5,310,022
	[3] 1900	36	14,970,745	384	459,449	8,809	5,938,734

[1] Includes value of rented property—1905, $473,000; 1900, $165,000.
[2] Includes establishments distributed as follows: Illinois, 1; Indiana, 4; Kentucky, 1; Maryland, 2; Michigan, 1; Missouri, 1; New York, 2; Ohio, 7; West Virginia, 6.
[3] Includes establishments distributed as follows: Illinois, 5; Indiana, 5; Kentucky, 1; Maryland, 3; Michigan, 1; Missouri, 1; New York, 4; Ohio, 12; Virginia, 1; West Virginia, 3.

The cost of materials and the value of products have been omitted from this table, as it is impracticable to show these items by states without duplication; black plates produced in one state, and therefore credited to that state as products, being often consumed in other states by tin and terne dipping establishments and their value consequently reappears in the value of products of such states.

The proportional number of establishments in Pennsylvania decreased from 45.5 per cent of the total in 1900 to 43.2 per cent in 1905. All the other items show an increase proportionately—capital, from 45.5 per cent in 1900 to 46 per cent in 1905; salaried officials, from 47.1 per cent to 63.4 per cent; salaries, from 43.8 per cent to 63.3 per cent; wage-earners, from 40.6 per cent to 49.6 per cent; and wages, from 42.3 per cent to 49.7 per cent.

Table 5 is a comparative summary of the materials used by the tin and terne dipping and black plate establishments for 1900 and 1905, with the per cent of increase.

TABLE 5.—COMBINED INDUSTRY—MATERIALS USED, BY KIND, QUANTITY, AND COST, WITH PER CENT OF INCREASE: 1905 AND 1900.

KIND.	Unit of measure.	1905		1900		PER CENT OF INCREASE.	
		Quantity.	Cost.	Quantity.	Cost.	Quantity.	Cost.
Aggregate			[1] $49,016,487		[1] $45,004,716		8.9

Charcoal	Bushels	156,800	13,325	12,926	730		
Natural gas			293,795		328,388		
Oil	Barrels	2,422	4,238	50	1,061		
Fuel for power			704,399		[3]		
All other materials			808,296		2,911,253		

[1] Includes a duplication equal to the cost of the domestic black plates, products of the black plate industry and used as material in the tin and terne dipping industry.
[2] Decrease.
[3] Not reported separately.

The tin and lead contents of terne mixture, when purchased in 1905, were entered separately at current values in the census returns for that year, but at the census of 1900 terne mixture, when purchased, was in some cases reported as "pig tin" and in other cases as "pig lead." For this reason the quantities and values of tin and lead, as reported for 1900, are not strictly comparable with those for 1905, except when combined.

The heavy increase in the quantity of domestic black plates used—an increase of 193,967,765 pounds, or 23.5 per cent—and the decrease in the quantity of foreign plates used—from 2,358,607 pounds to 83,900 pounds—are worthy of notice.

The average cost of the domestic black plates used by tin and terne plate establishments in 1905 was 2.25 cents per pound, as compared with 2.49 cents per pound in 1900; and the average value of the black plates turned out by the rolling mills in 1905 was 2.24 cents per pound, as compared with 2.38 cents per pound in 1900. The average value of the iron black plates made by rolling mills in 1905 was 1.96 cents per pound; of the Bessemer steel black plates, 2.31 cents per pound; and of the open-hearth steel black plates, 2.17 cents per pound. In 1900 there were no iron black plates reported as manufactured, and the Bessemer steel black plates were of an average value of 2.35 cents per pound and the open-hearth steel black plates 2.63 cents per pound.

Table 6 shows the value of the net products of the tin and terne plate dipping and black plate establishments for 1900 and 1905, with the per cent of increase.

TABLE 6.—*Combined industry—net value of products, with per cent of increase: 1905 and 1900.*

INDUSTRY.	PRODUCTS (NET VALUE).		Per cent of increase.
	1905	1900	
Total	$42,690,880	$41,322,053	3.3
Tin and terne dipping	35,283,360	31,892,011	10.6
Black plate[1]	7,407,520	9,430,042	[2]21.4

[1] Does not include $22,968,237 in 1905 and $20,590,566 in 1900, the value of black plates consumed by tin and terne dipping establishments.
[2] Decrease.

Duplication has been largely avoided by omitting the value of the domestic black plates consumed by the tin and terne plate dipping industry from the products of the black plate industry.

Some duplications remain, however, but they are of a minor character and the values of all products for each census year are substantially correct.

The products of the black plate industry remaining after the exclusion of the black plates consumed by tin and terne dipping establishments include the black plates otherwise used and all other products of the rolling mills making black plates. The slight increase in the value of net products of 3.3 per cent is due to the considerable decrease in the value of the excess of the products of the black plate establishments over and above the black plates consumed by tin and terne dipping establishments.

THE TIN AND TERNE DIPPING INDUSTRY.

The statistics included under this head are those for establishments which buy black plates and coat them, or for the dipping department only in the case of plants which both manufacture and dip black plates.

Table 7 is a comparative summary of the general statistics of the tin and terne dipping industry for 1900 and 1905.

TABLE 7.—*Tin and terne dipping industry—comparative summary, with per cent of increase: 1905 and 1900.*

	1905	1900	Per cent of increase.
Number of establishments	36	57	[1]36.8
Capital	[2]$10,891,239	[2]$6,790,047	60.4
Salaried officials, clerks, etc., number	284	333	[1]14.7
Salaries	$309,554	$291,323	6.3
Wage-earners, average number	4,847	3,671	32.0
Total wages	$2,383,070	$1,889,917	26.1
Men 16 years and over	4,212	3,014	39.7
Wages	$2,193,062	$1,711,475	28.1
Women 16 years and over	579	625	[1]7.4
Wages	$179,917	$172,568	4.3
Children under 16 years	56	32	75.0
Wages	$10,091	$5,874	71.8
Miscellaneous expenses	$389,873	$236,456	64.9
Cost of materials used	$31,375,714	$26,728,150	17.4
Value of products	$35,283,360	$31,892,011	10.6

[1] Decrease.
[2] Includes value of rented property—1905, $78,000; 1900, $140,000.

A noticeable concentration of the industry is shown in this table. Although the number of establishments decreased 36.8 per cent, the capital increased 60.4 per cent and the value of products 10.6 per cent. The advance in wages did not keep pace with the increase in wage-earners, but the amount paid for salaries showed an increase, though the number of salaried officials decreased.

Table 8 presents the statistics relating to the capital of both active and idle tin and terne dipping establishments for the censuses of 1900 and 1905.

TABLE 8.—*Tin and terne dipping industry—active and idle establishments—capital: 1905 and 1900.*

	Census.	Number of establishments.	CAPITAL.			
			Total.	Land.	Buildings, machinery, tools, and implements.	Cash and sundries.
Total	1905	[1]41	[2]$11,339,049	$403,100	$5,189,297	$5,746,652
	1900	59	[2]6,817,272	539,125	2,650,540	3,627,607
Active	1905	36	10,891,239	386,000	4,774,873	5,730,366
	1900	57	6,790,047	528,400	2,634,040	3,627,607
Idle	1905	5	447,810	17,100	414,424	16,286
	1900	2	27,225	10,725	16,500	.....

[1] Not including 8 establishments, 6 of which are idle and attached to rolling mills, and 2 classified as "tinware;" capital not reported separately.
[2] Includes value of rented property—1905, $78,000; 1900, $140,000.

The increase in capital, $4,521,777, or 66.3 per cent, is in the main almost equally divided between equipment, as represented by buildings, machinery, tools, and implements, which have increased $2,538,757, and live capital, which has increased $2,119,045. In 1905 the capital invested in idle plants constituted 3.9 per cent of the total, as compared with four-tenths of 1 per cent in 1900.

Table 9 is a comparative summary of the statistics of the tin and terne dipping industry for the state of Pennsylvania and "all other states" for 1900 and 1905. As before stated, the statistics for states other than Pennsylvania can not be given separately without disclosing the operations of individual owners.

TABLE 9.—TIN AND TERNE DIPPING INDUSTRY—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
				Number.	Salaries.	Average number.	Wages.			
United States	1905	36	[1] $10,891,239	284	$309,554	4,847	$2,383,070	$389,873	$31,375,714	$35,283,360
	1900	57	[1] 6,790,047	333	291,323	3,671	1,889,917	236,456	26,728,150	31,802,011
Pennsylvania	1905	19	4,700,369	191	218,980	2,421	1,206,781	231,376	17,590,077	19,341,961
	1900	25	3,042,029	189	147,202	1,578	813,692	82,169	10,364,084	12,530,901
All other states	[2] 1905	17	6,190,870	93	90,574	2,426	1,176,289	158,497	13,785,637	15,941,399
	[3] 1900	32	3,748,018	144	144,121	2,093	1,076,225	154,287	16,364,066	19,361,020

[1] Includes value of rented property—1905, $78,000; 1900, $140,000.
[2] Includes establishments distributed as follows: Indiana, 3; Maryland, 1; Michigan, 1; Missouri, 1; New York, 2; Ohio, 5; West Virginia, 4.
[3] Includes establishments distributed as follows: Illinois, 3; Indiana, 5; Kentucky, 1; Maryland, 2; Michigan, 1; Missouri, 1; New York, 4; Ohio, 12; Virginia, 1; West Virginia, 2.

Pennsylvania advanced considerably in importance in the industry during the five-year period from 1900 to 1905, for, notwithstanding a slight decrease in proportion of the total capital invested in the industry, the proportion of the total value of product assignable to the state increased from 39.3 per cent in 1900 to 54.8 at the census of 1905, and at the latter census about one-half of all the wage-earners reported for the industry in the United States were employed in the tin and terne plate mills of Pennsylvania.

The kind, quantity, and cost of materials used in the tin and terne plate industry in 1900 and 1905 are shown in Table 10, with the percentage of increase for the different items.

TABLE 10.—TIN AND TERNE DIPPING INDUSTRY—MATERIALS USED, BY KIND, QUANTITY, AND COST, WITH PER CENT OF INCREASE: 1905 AND 1900.

KIND.	Unit of measure.	1905		1900		PER CENT OF INCREASE.	
		Quantity.	Cost.	Quantity.	Cost.	Quantity.	Cost.
Aggregate			$31,375,714		$26,728,150		17.4
Domestic black plates or sheets for tinning, total	Pounds	1,019,524,757	22,988,237	825,556,992	20,590,566	23.5	11.6

[1] Not reported separately.
[2] Decrease.

The total quantity of black plates consumed, both domestic and foreign, was 1,019,608,657 pounds in 1905, as against 827,915,599 pounds in 1900, an increase of 191,693,058 pounds, or 23.2 per cent. The imported black plates in 1905 constituted less than one one-hundredth of 1 per cent of the total amount used, as against a little less than three-tenths of 1 per cent in 1900. In 1905 the foreign plates were used in Penn-

sylvania, and in 1900 in Pennsylvania and Virginia. The black plates formed 73.3 per cent of the cost of all material in 1905 and 77.3 per cent in 1900.

As already explained, the quantity and cost of tin and lead in 1905 are not strictly comparable with those items in 1900, on account of the difference at the two censuses in the method of reporting terne mixture. The fuels reported by kinds are, likewise, not comparable, except for the total cost, inasmuch as fuel used for power was classified separately in 1905 and not distributed among the several kinds of fuel as in 1900. The difference between the total quantity of tin or terne plated products, shown in Table 11, and the quantities of black plates, pig tin, and pig lead used, indicates a loss of 1.9 per cent in the process of tin and terne dipping.

Table 11 shows the quantity and value of the products of the tin and terne dipping establishments for the state of Pennsylvania and "all other states" for 1900 and 1905.

TABLE 11.—TIN AND TERNE DIPPING INDUSTRY—COMPARATIVE SUMMARY OF PRODUCTS, BY STATES: 1905 AND 1900.

STATE.	Census.	Total value.	TIN PLATES.		TERNE PLATES.		OTHER SHEET IRON AND SHEET STEEL, TIN OR TERNE PLATED.		All other products, including amount received for custom work and repairing.

[1] Includes establishments distributed as follows: Indiana, 3; Maryland, 1; Michigan, 1; Missouri, 1; New York, 2; Ohio, 5; West Virginia, 4.
[2] Includes establishments distributed as follows: Illinois, 3; Indiana, 5; Kentucky, 1; Maryland, 2; Michigan, 1; Missouri, 1; New York, 4; Ohio, 12; Virginia, 1; West Virginia, 2.

The total production in 1905 was 1,032,940,706 pounds of tin and terne plates or sheets of all kinds, valued at $34,767,019, as against 850,004,495 pounds, valued at $31,370,637, in 1900, an increase of 182,936,211 pounds in quantity, or 21.5 per cent, and of $3,396,382 in value, or 10.8 per cent.

In 1905 tin plates constituted 84 per cent in quantity of the tin or terne plated output; terne plates, 15.4 per cent; and other sheet iron and sheet steel, tin or terne plated, six-tenths of 1 per cent, as against 83.3 per cent for tin plates, 16.6 per cent for terne plates, and one-tenth of 1 per cent for other tin or terne plated iron and steel sheets in 1900.

The average value of tin plate was 3.28 cents per pound, as against 3.61 cents in 1900; the average value of the terne plates was 3.85 cents per pound, as against 4.06 cents in 1900; and the average value of other sheet iron and sheet steel, tin or terne plated, was 3.32 cents per pound, as against 8.65 cents in 1900.

There has been a heavy increase in tin plate production in Pennsylvania during the period, amounting to 268,026,590 pounds, or 104.3 per cent. The state produced 60.5 per cent of the total tin plate product of the country in 1905, as against 36.3 per cent in 1900.

Table 12 shows for tin plates, terne plates, taggers tin, etc., the total domestic production and consumption, the imports, the exports of domestic and of foreign origin, and the percentage of the domestic consumption supplied by imported plates, for the quinquennial periods from 1890 to 1905.

TABLE 12.—TIN PLATE, TERNE PLATE, AND TAGGERS TIN PRODUCED, IMPORTED, EXPORTED, AND RETAINED FOR CONSUMPTION: 1890 TO 1905.[1]

YEAR.	Production (pounds).	Exports of domestic (pounds).	Domestic retained for consumption (pounds).	Imports (pounds).	Exports of foreign (pounds).	Total retained for consumption (pounds).	Per cent of imports to total consumption.

[1] Bureau of Statistics, Department of Commerce and Labor, "Statistical Abstract of the United States," 1905.
[2] Production according to Census returns.
[3] Not reported separately.

The tin plate industry was of very small proportions in the United States in 1890; very few tin and terne plates were made for sale, and the market was practically supplied by imports. The establishment of the industry dates from 1891, when the output was about 2,236,000 pounds. The first export of domestic plates was made in 1898, the amount being 20,827 pounds; in 1900 the amount had increased to 319,579 pounds, while in 1905 it was 22,990,816 pounds, a gain for the last five years of more than seventyfold. The net amount retained for consumption increased for the five-year period 1900 to 1905, 174,037,668 pounds, or 17.5 per cent, and the domestic production increased 182,936,211 pounds, or 21.5 per cent.

Table 13 shows the equipment of all tin and terne dipping establishments, whether active or idle, and the daily capacity of the plants in pounds of tin and terne plates, on single turn, for the years 1900 and 1905.

TABLE 13.—TIN AND TERNE DIPPING INDUSTRY—ACTIVE AND IDLE ESTABLISHMENTS—NUMBER, EQUIPMENT, AND DAILY CAPACITY, BY STATES: 1905 AND 1900.

[1] Includes 8 establishments and equipments not included in other tables, of which 6 are idle and attached to rolling mills and 2 to establishments classified as "tinware," distributed as follows: Indiana, 1; Illinois, 2; Kentucky, 1; Pennsylvania, 2; Virginia, 1; WestVirginia, 1.
[2] Not reported separately.
[3] Includes 6 plants reported as 3 establishments.

There is included in the above table the equipment of 8 establishments which do not figure in the other tables. Of these, 6 are idle tin or terne dipping plants attached to rolling mills and 2 are dipping plants in establishments making tinware and so classified. There are 24 plants in Pennsylvania, although only 21 are credited to this state, 6 plants having been covered by three reports in making the returns for 1905. Hence in the aggregate there are 52 completed tin and terne dipping plants in 1905, as against 59 in 1900.

On the basis of three hundred working days for the year the tin and terne plate product for 1905 was 76 per cent of the capacity of all establishments on single turn; the output of tin plates being 77 per cent of the annual capacity and the terne plate product, 70.5 per cent.

The majority of the active establishments operated in 1905 on double turn. There were 8 establishments on single turn, which as a rule is ten hours; 21 on double turn; 7 on triple turn, eight hours to a crew; and 5 establishments were idle during the year. There were 23 establishments equipped for the manufacture of both tin and terne plates, 20 establishments for the manufacture of tin plates only, and 6 for the manufacture of terne plates only. Thus 43 plants had tin plate and 29 terne plate equipments. In 1900, of the 59 active and idle plants, 35 were equipped for the manufacture of both tin and terne plates, 15 for the manufacture of tin plates only, and 9 terne plates only; or 50 for the manufacture of tin plates and 44 for the manufacture of terne plates.

A detailed summary of the statistics of the active establishments is presented for Pennsylvania and "all

other states" in Table 20 at the end of this report. The table does not include the statistics of 2 dipping equipments in Illinois attached to establishments making tinware and so classified.

The statistics for the 5 idle tin and terne dipping establishments for which reports are available are shown in Table 21 at the end of this report. Four of these establishments are located in Ohio and 1 in West Virginia. This table is exclusive of 6 idle dipping plants attached to rolling mills, where a separation of capital has not been made. Of these establishments, 1 is in Indiana, 1 in Kentucky, 2 in Pennsylvania, 1 in Virginia, and 1 in West Virginia.

THE BLACK PLATE INDUSTRY.

Black plates or sheets for tinning are a product of the rolling mill, and the statistics therefor are included in those for steel works and rolling mills in the report on the iron and steel industry. The following statistics are those of the rolling mills which make black plates or sheets for tinning, either solely or in connection with other rolling mill products.

Table 14 is a comparative summary of the statistics of the black plate industry for 1900 and 1905.

TABLE 14.—*Black plate industry—comparative summary, with per cent of increase: 1905 and 1900.*

	1905	1900	Per cent of increase.
Number of establishments	35	44	[1] 20.5
Capital	[2] $21,566,248	[2] $20,698,255	4.2
Salaried officials, clerks, etc., number	577	393	46.8
Salaries	$627,128	$526,692	19.1
Wage-earners, average number	12,317	11,155	10.4
Total wages	$8,176,653	$8,398,144	[1] 2.6
Men 16 years and over	12,167	10,784	12.8
Wages	$8,145,308	$8,285,364	[1] 1.7
Women 16 years and over	29	63	[1] 54.0
Wages	$5,454	$21,266	[1] 74.4
Children under 16 years	121	308	[1] 60.7
Wages	$25,891	$91,514	[1] 71.7
Miscellaneous expenses	$1,425,415	$268,672	430.5
Cost of materials used	$17,640,773	$18,276,566	[1] 3.5
Value of products	$30,395,757	$30,020,608	1.2
Black plates	$25,297,079	$20,967,805	20.6
All other products	$5,098,678	$9,052,803	[1] 43.7

[1] Decrease.
[2] Includes value of rented property—1905, $395,000; 1900, $25,000.

The products of this industry include at the census of 1905 black plates valued at $25,297,079, or 83.2 per cent of all products, and in 1900 black plates valued at $20,967,805, or 69.8 per cent of all products. "All other products" in 1900 included plates and sheets other than black plates having a value of $4,517,644, and in 1905 there is included in "all other products" boiler and other plates and sheets having a value of $3,941,563 and scrap sold amounting to $1,041,949.

There was a decrease in the number of establishments making black plates in 1905 as compared with 1900, but the total products in 1905 show a small increase over the products in 1900, and the black plate product shows a very material increase, the percentage of increase being 20.6.

The proportionate increase in miscellaneous expenses is apparently very large, but the amount reported for miscellaneous expenses by rolling mills making black plates in 1900 constituted but 1 per cent of the total expense; whereas in the industry as a whole—"steel works and rolling mills"—miscellaneous expenses constituted 4.7 per cent of all expenses reported. In 1905 miscellaneous expenses as reported by the black plate rolling mills is 5.1 per cent of all expense, as compared with 6 per cent for all steel works and rolling mills.

The statistics of capital invested in the active and idle black plate establishments in 1900 and 1905 are presented in detail in Table 15.

TABLE 15.—*Black plate industry—active and idle establishments—capital: 1905 and 1900.*

CLASS.	Census.	Number of establishments.	CAPITAL. Total.	Land.	Buildings, machinery, tools, and implements.	Cash and sundries.
Total	1905	41	[1] $22,420,852	$1,273,880	$13,042,454	$8,104,518
	1900	44	[1] 20,698,255	1,367,000	12,446,725	6,884,530
Active	1905	35	21,566,248	1,225,380	12,274,454	8,066,414
	1900	44	20,698,255	1,367,000	12,446,725	6,884,530
Idle	1905	6	854,604	48,500	768,000	38,104
	1900	.....	.....	.....	.....	.....

[1] Includes value of rented property—1905, $395,000; 1900, $25,000.

The increase from 1900 to 1905 in the amount of capital invested in these establishments was not large—only 8.3 per cent. The part invested in land decreased, while that invested in equipment increased only 4.8 per cent. The capital invested in idle establishments, nearly 90 per cent of which was in the form of equipment, amounted to only 3.8 per cent of the total.

Table 16 presents the statistics of the industry for Pennsylvania and "all other states" for 1900 and 1905.

TABLE 16.—BLACK PLATE INDUSTRY—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
				Number.	Salaries.	Average number.	Wages.			
United States	1905	35	[1] $21,566,248	577	$627,128	12,317	$8,176,653	$1,425,415	$17,640,773	$30,395,757
	1900	44	[1] 20,698,255	393	526,692	11,155	8,398,144	268,672	18,276,566	30,020,608

All other states	[2] 1905	19	11,323,925	222	253,642	6,227	4,133,733	692,670	8,581,521	14,716,021
	[3] 1900	22	11,222,727	240	315,328	6,716	4,862,509	201,724	11,567,916	18,872,949

[1] Includes value of rented property—1905, $395,000; 1900, $25,000.
[2] Includes establishments distributed as follows: Illinois, 1; Indiana, 4; Kentucky, 1; Maryland, 1; Ohio, 7; West Virginia, 5.
[3] Includes establishments distributed as follows: Illinois, 3; Indiana, 5; Kentucky, 1; Maryland, 1; Missouri, 1; Ohio, 9; West Virginia, 2.

In the black plate as well as in the other branch of the industry, Pennsylvania is much the most important state, reporting 47.5 per cent of the total capital, 50 per cent of the total number of salaried officials, clerks, and wage-earners, and 51.6 per cent of the total value of products. Within the state itself the number of establishments decreased, but all the other items showed considerable increases.

The cost of materials used in the manufacture of black plates in 1900 and 1905 is shown in Table 17.

TABLE 17.—BLACK PLATE INDUSTRY—MATERIALS USED, BY KIND, QUANTITY, AND COST, WITH PER CENT OF INCREASE: 1905 AND 1900.

KIND.	Unit of measure.	1905		1900		PER CENT OF INCREASE.	
		Quantity.	Cost.	Quantity.	Cost.	Quantity.	Cost.
Aggregate			$17,640,773		$18,276,566		[1] 3.5
Iron ore	Tons			1,035	6,916		
Pig iron, spiegeleisen and ferromanganese	Tons			16,514	253,920		
Old iron or steel rails and other scrap iron or steel	Tons	11,630	148,776	34,422	592,222	[1] 66.2	[1] 74.9
Iron or steel ingots, blooms, billets, tin-plate bars, sheet bars and slabs	Tons	662,887	15,440,072	648,807	13,911,080	2.2	11.0
Fuel, total			1,330,621		869,070		53.1
Bituminous coal and slack	Tons	237,409	383,809	563,065	571,186		
Coke	Short tons	858	2,397	1,870	2,628

Natural gas			236,797		294,278		
Oil	Barrels	2,422	4,238	50	361		
Fuel for power			690,055		[2]		
All other materials			721,304		2,643,358		

[1] Decrease.
[2] Not reported separately.

Although, as has been shown, the value of products increased slightly from 1900 to 1905, the total cost of materials decreased 3.5 per cent. In 1905 no iron ore or pig iron, etc., was reported as purchased, and the amount of iron or steel scrap used decreased largely. For the census of 1905 the cost of fuel used for power was reported separately, amounting to $690,055, but the kinds and quantities of fuel so used were not stated. Hence a comparison with 1900 can only be made as to the total expenditures for fuel, which amounted to $1,330,621 in 1905 and to $869,070 in 1900. Natural gas was used as fuel in whole or in part by 18 establishments, of which 2 were located in Indiana, 3 in Ohio, 10 in Pennsylvania, and 3 in West Virginia.

Table 18 shows in detail the products of the black plate industry for Pennsylvania and "all other states" for 1900 and 1905.

TABLE 18.—BLACK PLATE INDUSTRY—COMPARATIVE SUMMARY OF PRODUCTS, BY STATES: 1905 AND 1900.

	Census.	Total value.	BLACK PLATES.								ALL OTHER PLATES AND SHEETS.		All other products.
			Total.		Iron.		Bessemer steel.		Open-hearth steel.		Tons.	Value.	
			Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.

[1] Includes establishments distributed as follows: Illinois, 1; Indiana, 4; Kentucky, 1; Maryland, 1; Ohio, 7; West Virginia, 5.
[2] Includes establishments distributed as follows: Illinois, 3; Indiana, 5; Kentucky, 1; Maryland, 1; Missouri, 1; Ohio, 9; West Virginia, 2.

In 1900 no iron black plates were reported, and nine-tenths of the black plates were made of Bessemer steel and one-tenth of open-hearth steel. In 1905, 70 per cent of these plates were made of Bessemer steel, 17.2 per cent of open-hearth steel, and 12.7 per cent of iron. The black plates show an increase in 1905, as compared with 1900, of 27.9 per cent in quantity and 20.6 per cent in value. The average value of all kinds of black plates in 1905 was $50.19 per ton, as compared with $53.22 per ton in 1900. The iron black plates show an average value of $43.83 per ton; Bessemer steel, $51.76 per ton; and open-hearth steel, $48.52 per ton. In 1900 the average value of the Bessemer black plates was $52.59 per ton, and of the open-hearth steel black plates $58.93 per ton. There is included in the "value of all other products" the billets, tin-plate bars, and sheet bars produced for sale by the rolling mills making black plates, valued at $53,230 in 1905, also iron and steel scrap sold having a value of $1,041,949. In 1900 the billets and sheet and tin-plate bars included in "all other products" amounted to $1,894,000.

The black plate product of the state of Pennsylvania increased 49 per cent in 1905, as compared with 1900, and this state contributed 52.8 per cent of all black plates manufactured in the country in 1905, as against 45.3 per cent in 1900.

Table 19 shows the hot and cold mill equipment, by states, of the active and idle rolling mill establishments producing black plates, and the annual capacity of the hot mills, for 1900 and 1905.

TABLE 19.—*Black plate industry—active and idle establishments—number, equipment, and capacity, by states: 1905 and 1900.*

STATE.	Census.	Number of establishments.	Number of hot mills.	Number of cold mills.	Annual capacity of hot mills (tons).
United States	1905	41	406	334	958,455
	1900	44	332	294	641,450
Ohio	1905	9	81	71	183,581
	1900	8	59	58	114,525
Pennsylvania	1905	17	209	173	491,408
	1900	23	160	157	314,325
West Virginia	1905	5	43	33	105,098
	1900	2	14	14	27,250
All other states	[1]1905	10	73	57	178,368
	[2]1900	11	99	65	185,350

[1] Includes establishments distributed as follows: Illinois, 1; Indiana, 6; Kentucky, 1; Maryland, 1; Wisconsin, 1.
[2] Includes establishments distributed as follows: Illinois, 3; Indiana, 5; Kentucky, 1; Maryland, 1; Missouri, 1.

The above table includes completed mills only. There has been an increase in each state for which details are given in numbers of hot and cold mills, and in the annual capacity of the hot mills. In 1905 the black plate product equaled 52.6 per cent of the capacity of the hot plate mills, as compared with 61.4 per cent in 1900.

TABLE 20.—*Tin and terne plate—detailed summary, by states: 1905.*

	United States.	Pennsylvania.	All other states.[1]
Number of establishments	36	19	17
Capital, total	$10,813,239	$4,692,369	$6,120,870

COPPER, LEAD, AND ZINC, SMELTING AND REFINING

COPPER, LEAD, AND ZINC, SMELTING AND REFINING.

By STORY B. LADD.

The smelting and refining of ores was first treated as manufacturing at the census of 1870. Prior thereto the statistics for mining and the milling and smelting and refining of ores were combined, and no segregation was made of the statistics relating to mining and milling and those bearing on the manufacturing side of the industry. At the census of 1870 a separation of the industry was made, and the treatment of the ores after delivery from the mines was classed as manufacturing, but at the census of 1890 smelting and refining was reported as an adjunct to the mining industry, and no attempt was made to secure data in harmony with the returns secured from manufacturing establishments. Under the act of Congress for taking the Twelfth and subsequent censuses the smelting and refining of ores is considered a manufacturing industry, and a full presentation of the statistics for lead, copper, and zinc smelting and refining was made at the Twelfth Census.

It is possible to present statistics for the present census comparable with those of 1900, but not with those for censuses prior thereto.

Copper and lead ores constitute the medium through which the precious metals contained in the bulk of the dry ores reach the refineries. Copper and lead ores not only often carry gold and silver values, but gold and silver ores deficient in base metal, or "dry ores," so called, are smelted with lead or copper ores to facilitate the extraction of the precious metals from the dry ores. Hence the gold and silver products are relatively large and in the case of the argentiferous lead smelters they exceed the base metal values.

In order to show the total quantities and cost of ore and matte or crude metal treated and of finished products manufactured, the ores and matte or crude metal smelted and refined under contract are reported, both as to quantities and cost of materials and value of products, as if bought by the reporting establishments, and in addition the amounts received for contract smelting or refining are reported.

With the exception of the smelting of nickel, tungsten, and molybdenum ores, and the few products of electric smelting, the statistics herewith presented cover all data relating to the smelting of ores and the refining of the products, with the exception of those relating to iron, which will be found in the special report on iron and steel.

The period covered by this report is the calendar year 1904, or the business year of the establishment reporting which most nearly conforms thereto. At the census of 1900 the period covered was from June 1, 1899 to May 31, 1900. The short ton is used unless otherwise stated.

THE COMBINED INDUSTRY.

Table 1 is a summary of the leading statistics of the copper, lead, and zinc smelting and refining industries for 1900 and 1905, showing the combined totals and the per cent of increase for the five-year period for the combined industry and the several sections.

TABLE 1.—COPPER, LEAD, AND ZINC, SMELTING AND REFINING—COMPARATIVE SUMMARY, BY INDUSTRIES, WITH PER CENT OF INCREASE: 1905 AND 1900.

	TOTAL.		COPPER.		LEAD.		ZINC.		PER CENT OF INCREASE.

[1] Decrease.

At the census of 1900 the lead smelting and refining industry was in the van, and copper occupied second place, but the positions have since been reversed.

The increase in capital in both the copper and zinc

industries is large, and proportionately the greater in the latter, whereas in the lead industry there is shown a decrease. The same holds true of the average number of wage-earners employed, the copper and zinc industries showing increased numbers, the largest increase being in the zinc industry, whereas the lead industry shows a decrease. With respect to the value of products both the actual and proportionate increase was greatest in the copper industry.

The following tabular statement shows the per cent of the total capital, wage-earners, and value of products, represented by the copper, lead, and zinc industries, for 1900 and 1905:

INDUSTRY.	1905			1900		
	Capital	Wage-earners.	Value of products.	Capital.	Wage-earners	Value of products.
Total	100.0	100.0	100.0	100.0	100.0	100.0
Copper	46.8	47.5	53.3	38.1	46.2	46.0
Lead	38.8	28.2	41.2	51.8	33.9	48.9
Zinc	14.4	24.3	5.5	10.1	19.9	5.1

The statistics for the zinc smelting industry show the straight growth of that industry. The statistics for the copper and lead smelting industries are, however, colored by the practice of smelting dry ores of the precious metals along with these base ores, and a large increase in the consumption of dry ores by copper smelters at the expense of the lead smelters has helped to swell the growth of the copper smelting and refining industry.

This is shown by the following statement, which gives the gold and silver production of the copper smelting and refining, and lead smelting and refining industries, for the censuses of 1900 and 1905, and shows also the copper product of the former industry, exclusive of Lake copper, and the lead product of the latter industry, exclusive of soft lead, which exclusions are made for the reason that dry ores, so called, are not smelted in conjunction with Lake copper ores or "mineral," or soft lead ores. The statement also gives the increase of the several products for the period 1900 to 1905, and the per cent of increase:

Copper and lead, smelting and refining—quantity of principal products, with amount and per cent of increase: 1905 and 1900.

KIND.	QUANTITY.				INCREASE.		PER CENT OF INCREASE.	
	Copper smelting and refining.		Lead smelting and refining.		Copper smelting and refining.	Lead smelting and refining.	Copper smelting and refining.	Lead smelting and refining.
	1905	1900	1905 [1]	1900				
Silver, ounces fine	28,115,790	13,229,911	71,920,997	70,420,917	14,885,879	1,500,080	112.5	2.1
Gold, ounces fine	636,207	224,352	2,543,757	2,514,836	411,855	28,921	183.6	1.2
Copper, not including Lake copper, pounds	728,620,468	444,654,289			283,966,179		63.9	
Lead, not including soft lead, pounds			613,331,956	497,455,931		115,876,025		23.3

[1] Duplication on account of Doré bars reported both as materials and products deducted; contents of same 671,990 ounces of silver, 30,792 ounces of gold.

It will be seen that the increase in the gold and silver products of the copper smelting and refining industry was very large and greatly in excess of the increase in the related copper product, although the latter increase is in itself large, 63.9 per cent; whereas the gains in the gold and silver products of the lead smelting and refining industry are very small and fall far below that for the related lead product.

The following statement further illustrates the change in smelting conditions and shows the total gold and silver production of the copper and lead smelters and refineries for 1900 and 1905 and the per cent of the total contributed by each class:

INDUSTRY.	SILVER (OUNCES FINE).		GOLD (OUNCES FINE).		PER CENT OF TOTAL.			
					Silver.		Gold.	
	1905	1900	1905	1900	1905	1900	1905	1900
Total	100,036,787	83,650,828	3,179,964	2,739,188	100.0	100.0	100.0	100.0
Copper smelting and refining	28,115,790	13,229,911	636,207	224,352	28.1	15.8	20.0	8.2
Lead smelting and refining	71,920,997	70,420,917	2,543,757	2,514,836	71.9	84.2	80.0	91.8

The silver output of the lead refineries shows a decrease from 84.2 per cent of the total silver product of the copper and lead refineries in 1900 to 71.9 per cent of the total for 1905, and a decrease in the gold output for the same period from 91.8 per cent to 80 per cent; while on the other hand the copper refineries show very heavy proportional gains in both silver and gold.

The increase in the consumption of dry ores by copper smelters appears to be due in part to the development of electrolytic copper refining whereby gold and silver values are easily and cheaply recovered, and also to the fact that, in the rapid advance in the art of matte smelting, copper has proved to be on the whole a better absorbent of the precious metals than lead.

COPPER SMELTING AND REFINING.

The general statistics of the copper smelting industry are shown in Table 2 for 1905 in comparison with like statistics for 1900.

TABLE 2.—*Copper smelting and refining—comparative summary, with per cent of increase: 1905 and 1900.*

	CENSUS.		Per cent of increase.
	1905	1900	
Number of establishments	40	47	[1]14.9
Capital	$76,824,640	$53,063,395	44.8
Salaried officials, clerks, etc., number	809	488	65.8
Salaries	$1,527,382	$954,905	60.0
Wage-earners, average number	12,752	11,324	12.6
Total wages	$10,827,043	$8,529,021	26.9
Men 16 years and over	12,702	11,272	12.7
Wages	$10,806,442	$8,509,895	27.0
Women 16 years and over		4	
Wages		$2,500	
Children under 16 years	50	48	4.2
Wages	$18,601	$16,626	11.9
Miscellaneous expenses	$4,748,399	$1,522,325	211.9
Cost of materials used	$196,736,986	$122,174,129	61.0
Value of products	$240,780,216	$165,131,670	45.8

[1] Decrease.

In addition to the active establishments shown in Table 2, there were 6 idle establishments reported at the census of 1905, located 1 each in Alaska, California, Colorado, Georgia, Montana, and Utah. The statistics are as follows:

TABLE 3.—*Copper smelting and refining—idle establishments: 1905.*

Number of establishments	6
Capital, total	$3,461,991
Land	$103,085
Buildings	$713,462
Machinery, tools, and implements	$663,976
Cash and sundries	$1,981,468
Power owned:	
Number of establishments reporting	5
Total horsepower	4,052
Engines—	
Steam—	
Number	15
Horsepower	3,060
Gas and gasoline—	
Number	3
Horsepower	128
Water wheels—	
Number	4
Horsepower	425
Water motors—	
Number	1
Horsepower	8
Electric motors—	
Number	17
Horsepower	431

At the census of 1900 there were 9 idle establishments with a capital of $371,320, located as follows: Arizona, 4; California, 1; Illinois, 1; and Nevada, 3.

The value of products as given in Table 2 is the aggregate of the products of all establishments, the smelters as well as the refineries, and such establishments as do both smelting and refining, and hence includes the duplication arising from the products of the smelters which appear as material for the refineries. The products of the refineries, or smelters combined with refineries, represent the finished products, the same including the product of the Lake ores.

The totals for the copper smelting industry as reported at the census of 1890 (Report on Mineral Industries), though too meager for comparison with later years, are given in Table 4.

TABLE 4.—*Copper smelting and refining: 1890.*

Capital, total	$4,037,593
Land	634,000
Buildings and fixtures	1,758,856
Tools, implements, etc	600,214
Cash, etc	1,044,523
Expenditures, total	1,885,261
Wages	800,484
Salaries	71,720
Paid contractors	19,591
Supplies and materials	737,098
Rent, interest, insurance, taxes, etc	256,368

In the absence of other statistics, the copper production can be taken as a gauge of the growth of the industry, and Table 5 shows the copper production from 1845 to 1904, inclusive.

The copper product of the United States for 1904, which is the year covered by the census of 1905, as reported to the United States Geological Survey, was 362,739 long tons. This includes the copper contents of blue vitriol and the copper product of lead smelters.

The refined copper product as reported at this census was 933,809,701 pounds, which is the copper product of the refineries and of the refineries combined with the smelters. (See Table 12.) There is included in this, however, a duplication of 23,829,109 pounds on account of material which, after treatment at some of the refineries, was sent for final treatment to others. To arrive at the copper product of the United States there is to be added the copper contents of the blue vitriol manufactured, estimated at one-fourth for copper contents, or 6,932,475 pounds; also the exports of copper in the form of matte, namely, 29,346,550 pounds, and further, there is to be deducted 91,743,719 pounds of refined copper produced from imported ore, matte, and pig copper. This gives 854,515,898 pounds as the product from mines located in the United States, or 381,480 long tons. Total quantity of Lake copper produced was 205,189,233 pounds.

The production of the smelters not connected with refineries contained 620,872,420 pounds of fine copper. This amount includes a duplication of 17,634,605 pounds, which represents the copper contents of matte shipped from certain of the smelters to others within the same class. After this duplication is eliminated the total product of the detached smelters contained 603,237,815 pounds of fine copper.

TABLE 5.—*Production of copper in the United States: 1845 to 1904.* [1]

YEAR.	Total (long tons).	LAKE SUPERIOR.		MONTANA.		ARIZONA.		ALL OTHER.	
		Quantity (long tons).	Per cent of total.	Quantity (long tons).	Per cent of total.	Quantity (long tons).	Per cent of total.	Quantity (long tons).	Per cent of total.

[1] United States Geological Survey, "Mineral Resources of the United States," 1904.

The following statement presents a comparison of the production of smelters and refineries:

	Pounds.
Total production of copper placed on the market	939,327,142
Production of smelters	603,237,815
Imported material treated by refineries in the United States	57,684,506
Total	660,922,321
Difference	278,404,821
	939,327,142

The total production of copper placed on the market is the refined copper product, less the duplication of 23,829,109 pounds above noted and plus the copper exported in the form of matte.

The difference between the product of the refineries on the one hand and the product of the smelters, together with imported material, on the other represents the production of pig copper by smelters connected with refineries. The total product of refined copper by the latter class of establishments was equal to 480,453,170 pounds, which can be classified as follows:

	Pounds.
Smelted and refined	278,404,821
Refined only	202,048,349
Total	480,453,170

Practically all of the copper matte product of the lead smelters, amounting to 51,617,670 pounds of contained copper, figures as material in the returns of the copper refineries, as also does 3,689,000 pounds of blister copper produced by an establishment engaged primarily in the manufacture of other products.

An estimate of the quantity of copper electrolytically refined is obtained by deducting from the total quantity placed on the market, the copper exported in the form of matte, and the Lake copper product less that portion of the latter which is electrolytically treated. This gives 754,693,459 pounds as the estimated production of electrolytic copper.

THE INDUSTRY, BY STATES AND TERRITORIES.

The general statistics, by states and territories, for the censuses of 1900 and 1905 are shown by Table 6.

All of the states and territories for which details can be presented show an increase in products with the exception of California. The statistics for Colorado and Montana are included under "all other states," and although there are in each state 3 or more establishments, the state details can not be given without disclosing individual operations, because two or more plants are owned by one corporation.

The very large increase for New Jersey in cost of materials used and value of products, along with a decrease in wage-earners, wages, and miscellaneous expenses, is due to the growth in electrolytic refining and decrease in smelting in the eastern establishments. This change in smelting and refining conditions will be further considered in treating of the eastern and western establishments.

TABLE 6.—COPPER SMELTING AND REFINING—COMPARATIVE SUMMARY, BY STATES AND TERRITORIES: 1905 AND 1900.

STATE OR TERRITORY.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
				Number.	Salaries.	Average number.	Wages.

[1] Decrease.

Table 7 shows the growth and concentration of the refining industry in the east which has been a marked feature of the copper industry for the last few years. The following statement shows the percentages of the total capital, wage-earners, cost of materials, and value of products represented by the eastern and western establishments for 1900 and 1905, and illustrates the changes in smelting and refining conditions:

	EAST OF THE MISSISSIPPI.		WEST OF THE MISSISSIPPI.	
	1905	1900	1905	1900
Capital	26.6	25.8	73.4	74.2
Wage-earners	34.7	36.1	65.3	63.9
Cost of materials used	70.7	71.1	29.3	28.9
Value of products	62.7	59.2	37.3	40.8
Smelting	0.7	2.1	99.3	97.9
Refining, including smelting and refining	98.8	86.8	1.2	13.2

It will be seen that the proportionate share of the refining done for 1905 by the establishments west of the Mississippi was but one-eleventh of what it was for 1900, and practically all of the refining was done in the east. The operations of the western establishments are now confined almost entirely to smelting, with, in a majority of cases, the conversion of the matte into blister copper, which is electrolytically refined in the east.

The eastern establishments show an increase in capital and value of products proportionally greater than the western establishments, with a slight decrease in proportionate share of cost of materials used and in average number of wage-earners.

The statistics, for 1905, of the refineries handling the Lake Superior product, the same including, however, the expense pertaining to the refining of 9,000 tons of Montana anodes not separable from the rest of the expense, are as follows:

Refining Lake Superior mineral: 1905.

Expenditures, total	$1,697,943
Wages	$606,487
Superintendence	$74,104
Fuel	$367,457
Supplies and materials, not including cost of "mineral"	$204,997
Rent, interest, insurance, etc	$444,898
"Mineral" treated, tons	164,756
Refined copper product, pounds	205,189,233

The mineral treated averaged 62.3 per cent copper as against 65.1 per cent for 1900, the decrease in average grade being due to the increase in utilization by concentration of the finer slimes of the stamp mills. If the Montana anodes which were refined are figured at par with the Lake copper, in order to give an approximation to the average cost of refining, it gives 0.761 of a cent as the average expenditure per pound of refined copper, as compared with 0.591 of a cent deduced at the census of 1900.

MATERIALS USED.

Table 8 exhibits the quantity and the cost of materials used, by kind, for the years 1900 and 1905, with the number of establishments reporting.

TABLE 8.—*Copper smelting and refining—materials used, by kind, quantity, and cost, with number of establishments reporting: 1905 and 1900.*

KIND.	Census.	Number of establishments reporting.	Tons.	Cost.
Total	1905	40	.....	$196,736,986
	1900	47	.....	122,174,129
Ores and concentrates	1905	34	7,361,473	60,402,094
	1900	33	4,524,033	25,190,522
Matte, purchased	1905	9	29,265	4,135,742
	1900	11	53,964	10,513,431
Blister or anodes, purchased	1905	9	372,607	111,248,191
	1900	13	318,102	72,401,654
All other materials, including fuel, mill supplies, etc.	1905	.....	.....	20,950,959
	1900	.....	.....	14,068,522

The consumption of ore shows an increase of 62.7 per cent in quantity, and blister or anodes, purchased, an increase of 17.1 per cent, while matte, purchased, shows a decrease of 45.8 per cent. The decrease in matte, purchased, is due to the more general use by the smelters of the Bessemerizing process and the conversion of their matte into blister copper, which is electrolytically refined by the refineries with a recovery of the precious metals contained in the crude copper.

Of the ores and concentrates consumed by all classes of smelters, 6,123,770 tons, valued at $38,884,183, were from mines operated by the same owners, and 1,237,703 tons, valued at $21,517,911, were purchased.

The consumption of copper yielding materials, by states, for the census years 1900 and 1905, is shown by Table 9.

TABLE 9.—*Copper smelting and refining—principal materials used by kind and quantity, and by states and territories: 1905 and 1900.*

STATE OR TERRITORY.	Census.	Ores and concentrates (tons).	Matte, purchased (tons).	Blister, or anodes purchased (tons).
United States	1905	7,361,473	29,265	372,607
	1900	4,524,033	53,964	318,102
Arizona	1905	1,231,468	3,349	.....
	1900	842,950	1,583	.....
California	1905	270,006	.....	.....
	1900	250,041	22	.....
Michigan	1905	[1] 128,119	.....	9,000
	1900	.....	.....	[1] 93,914
New Jersey	1905	345	2,796	169,435
	1900	4,218	33,351	81,611
Utah	1905	744,929	5,488	.....
	1900	73,127	.....	.....
All other states	[2] 1905	4,986,606	17,632	194,172
	[3] 1900	3,353,688	19,008	142,577

[1] "Mineral."
[2] Includes states as follows: Colorado, Idaho, Maryland, Montana, New York, Oregon, Tennessee, Virginia, Washington.
[3] Includes states as follows: Colorado, Connecticut, Illinois, Maryland, Montana, Nevada, New Mexico, New York, South Dakota, Tennessee, Virginia, Washington.

The Western states consumed 6,794,943 tons of ore, or 92.3 per cent of the total quantity, as compared with 4,367,777 tons, or 96.5 per cent, for 1900. Montana ranked first for 1905 with nearly six-tenths of the total

quantity of ores and concentrates smelted as compared with a little over six-tenths of the total quantity for 1900. As the details for Montana can not be shown in the general tables, on account of the ownership of all establishments by less than 3 corporations, the statistics for the state are included in "all other states" in all tables. Arizona was second with 16.7 per cent of the ores smelted for 1905 as compared with 18.6 per cent of all ores for 1900; Utah, third with 10.1 per cent; Tennessee, fourth; and California, which ranked third for 1900, fifth with 3.7 per cent. The refineries in New Jersey, New York, and Maryland make these states the largest consumers of matte and blister copper or anodes.

There were 24 establishments which reported only a consumption of ore for 1905 as compared with 26 in 1900; 6 which reported only matte and blister copper or anodes for 1905, as compared with 13 for 1900, and 10 which used both classes of material. Table 10 gives the comparative statistics, for 1900 and 1905, of all establishments according to this grouping, with the per cent of increase.

TABLE 10.—COPPER SMELTING AND REFINING—ESTABLISHMENTS CLASSIFIED ACCORDING TO KIND OF MATERIALS USED: 1905 AND 1900.

	TOTAL.		ESTABLISHMENTS USING ORES ONLY.		ESTABLISHMENTS USING MATTE AND BLISTER OR ANODES ONLY.		ALL OTHER ESTABLISHMENTS.		PER CENT OF INCREASE.

[1] Decrease.

Of the establishments which used ore only, 21 were smelters alone and 3 produced refined products. This group of establishments consumed 6,070,017 tons of ore, as compared with 4,143,865 tons for 1900, an increase of 46.5 per cent, and their products were 34,158 tons of refined copper, as compared with 47,702 tons for 1900; 246,954 tons of copper in matte and blister or anodes, as compared with 135,808 tons for 1900; 17,545,496 ounces of silver, as compared with 10,933,605 ounces for 1900; and 290,172 ounces of gold, as compared with 292,593 ounces for 1900.

The proportions which the different items of expenditures, viz, salaries, wages, miscellaneous expenses, and cost of materials, are of the total expense in the several groups of establishments may be deduced for comparative purposes. Table 11 shows, for 1900 and 1905, each item of cost and the percentage which it forms of the total cost for each of the foregoing groups or classes of establishments.

TABLE 11.—COPPER SMELTING AND REFINING—SALARIES, WAGES, MISCELLANEOUS EXPENSES, AND COST OF MATERIALS FOR ESTABLISHMENTS CLASSIFIED ACCORDING TO KIND OF MATERIALS USED, WITH PER CENT WHICH EACH ITEM FORMS OF TOTAL: 1905 AND 1900.

	1900	1,522,325	1.2	938,139	2.4	192,272	0.3	391,914	2.1
Cost of materials used	1905	196,736,986	92.0	52,017,764	82.2	78,660,651	98.0	66,058,571	93.9
	1900	122,174,129	91.7	32,028,770	82.0	74,103,544	97.6	16,041,815	88.0

In each group the proportionate share of the expense represented by labor has decreased, the decrease being relatively the largest in the group designated as "all other establishments," which are establishments that use both ores and matte, or blister copper, and in general do both smelting and refining. The labor factor is largest in establishments using ore only and smallest in the establishments using matte and blister or anodes only. Naturally the cost of materials used forms the largest proportionate share of the expense in the group of establishments which chiefly refine, a less per cent in the group using all classes of materials, and a still less per cent of the total in the group using ores only.

PRODUCTS.

The quantities and values of the products of the smelters and refineries, with the number of establishments producing each respective product, are shown in detail in Table 12 for the censuses of 1900 and 1905.

The fine copper contents of matte does not include matte produced as an intermediate product, but only matte produced and sold as such. The matte product of the smelters shows a decrease of 55,890,358 pounds in copper contents, or 40.6 per cent, for the period 1900 to 1905, while the copper product of smelters in form of blister copper or anodes increased 342,083,335 pounds, or 173.6 per cent. The change, as before noted, is due to the more extended use of converters and the Bessemerizing process. In 1900 there were 21 smelters which sold their product, in whole or in part, in the form of matte, while for 1905 there were only 12.

The smelting of 21,945,304 ounces of silver was reported by 23 copper smelting establishments for 1905, compared with 8,866,472 ounces of silver by 25 establishments in 1900; and 321,747 ounces of gold by 22 establishments for 1905, as against 300,914 ounces of gold by 23 establishments in 1900.

Ingots, wire, bars, etc.	1905	13	Pound	933,809,701	119,420,862
	1900	18	Pound	602,595,113	94,061,667
Blue vitriol	1905	5	Pound	27,729,900	1,120,368
	1900	7	Pound	27,298,926	1,225,745
Silver	1905	9	Ounce fine	28,115,790	16,034,886
	1900	11	Ounce fine	13,229,911	7,790,985
Gold	1905	7	Ounce fine	636,207	13,135,098
	1900	10	Ounce fine	224,352	4,556,850
All other products	1905				2,694,172
	1900				3,221,250

There were 9 refineries, or smelters and refineries combined, for 1905 which reported a product of 28,115,790 ounces of silver, as compared with 11 refineries in 1900, with 13,229,911 ounces of silver; and 7 reported 636,207 ounces of gold, as compared with 10

establishments, with a product of 224,352 ounces of gold in 1900.

There are two commercial methods of handling the materials shipped for treatment to smelters and refineries—they are either bought outright or treated on a toll basis. The cost of materials and the quantity and value of products shown in the present report combine both classes of materials—those bought and sold, as well as those treated on toll. The value of the products of materials treated on toll was estimated on the basis of the average prices reported by other establishments in the same locality, and the cost of materials was determined by deducting from the estimated value of the products the tolls received for treating them. The following statement shows the comparative prevalence of each method:

	COPPER PRODUCTION.		
	Total (pounds).	Returned to patrons (pounds).	Sold (pounds).
Smelters only	620,872,420	2,942,600	617,929,820
Refineries, with or without smelters	933,809,701	596,329,663	337,480,038

For 1905 there was received by the smelters $117,680 on account of contract smelting, as against $293,961 in 1900, and by the refineries or smelters and refineries the sum of $4,806,039, as against $3,452,855 in 1900; a total of $4,923,719 for 1905 as compared with a total of $3,746,816 in 1900, or an increase of 31.4 per cent.

Table 13 shows the quantities of each product for the two branches of the industry—smelting and refining—by states, for the censuses of 1900 and 1905.

TABLE 13.—COPPER SMELTING AND REFINING—PRINCIPAL PRODUCTS, BY KIND AND QUANTITY, AND BY STATES AND TERRITORIES: 1905 AND 1900.

[1] Included in "all other states."
[2] Includes states as follows: Colorado, Idaho, Maryland, Montana, New York, Oregon, Tennessee, Virginia, Washington.
[3] Includes states as follows: Colorado, Connecticut, Illinois, Maryland, Montana, Nevada, New Mexico, New York, South Dakota, Tennessee, Virginia, Washington.

The state of New Jersey continues to be the largest producer of refined copper with a large gain in its proportion of the total, its product constituting 35.6 per cent of the total in 1905 and 28.3 per cent in 1900. The refining industry in the state of New York has also made a very heavy advance, so that the states of New Jersey and New York refined nearly two-thirds of the copper product of the country. Michigan was third and Maryland fourth.

The states west of the Mississippi river produced 615,538,323 pounds of the fine copper contents of blister or anodes and matte, out of the total of 620,872,420 pounds, or 99.1 per cent, compared with 98 per cent in 1900.

PROCESS EMPLOYED—SMELTING, REFINING, AND SMELTING AND REFINING.

Table 14 presents the comparative statistics for 1900 and 1905 for the establishments grouped according to process employed—those doing smelting only, those doing refining only, and those doing both smelting and refining—with the per cent of increase for each group.

A comparison of the statistics shows a movement toward a separation of smelting and refining. There was a decrease of 36.2 per cent in the capital invested in refineries and in smelters combined with refineries, and an increase of 185.6 per cent in the capital invested in smelters; and the average number of wage-earners

employed by refineries and by smelters combined with refineries shows a decrease from 7,121 for 1900 to 4,327 for 1905, or 39.2 per cent, while the average number of wage-earners employed by smelters only has increased 100.5 per cent. The movement toward a separation of the two branches of the industry is further shown by the materials used. In 1900 the refineries and the smelters combined with refineries handled 2,403,547 tons of ore, costing $12,849,737, or an average of $5.35 per ton, and the establishments doing smelting only handled 2,120,486 tons of ore of an average cost of $5.82 per ton. For 1905, however, the smelters combined with refineries handled 461,022 tons of ore of an average cost of $45.12 per ton and the detached smelters 6,900,451 tons of an average cost of $5.74 per ton. That is, an increasing proportion of the smelting is being done by establishments which do smelting only, and the ores that go to establishments doing smelting and refining are high-grade ores or concentrates.

[1] Decrease.
[2] The contents of intermediate products of smelting department which constituted material for refining was: Copper, 12,578,417 pounds; silver, 485,598 ounces fine; gold, 66,086 ounces fine.

Table 15 shows, for the censuses of 1900 and 1905, the items of expense and the percentage which each is of the total for the establishments in each of the groups given in Table 14.

In the case of establishments doing smelting only the proportional expenditure for labor is larger than in the case of refineries and that for material less. In all groups the proportional expenditure for labor shows a decrease for 1905 over 1900 and that for materials, an increase; and further, the proportional expenditures for labor and materials for establishments doing both smelting and refining is approaching that of the establishments which do refining only.

TABLE 15.—COPPER SMELTING AND REFINING—SALARIES, WAGES, MISCELLANEOUS EXPENSES, AND COST OF MATERIALS FOR ESTABLISHMENTS CLASSIFIED ACCORDING TO PROCESS EMPLOYED, WITH PER CENT WHICH EACH ITEM FORMS OF TOTAL: 1905 AND 1900.

	Census.	TOTAL.		SMELTING.		REFINING.		SMELTING AND REFINING.

GROSS AND NET VALUE OF PRODUCTS.

The values of products hereinbefore considered are the net values at the works. In making the canvass for the census of 1905 it was desired to ascertain the gross value of the products as well as the net amount received, the former being the net value, plus the amount paid for treatment, and for freight on the product to the smelter or refinery, and for commissions and selling expense.

Table 16 shows, for the census of 1905, the gross and net values of products and the deductions for refining tolls, freight, and selling expense for establishments reporting the same, by states.

TABLE 16.—COPPER SMELTING AND REFINING—ESTABLISHMENTS REPORTING GROSS AND NET VALUES OF PRODUCTS: 1905.

	Number of establishments.	PRODUCTS.				DEDUCTIONS.				Products, net value.
		Total gross value.	Copper and copper contents.		Gold, silver, and other products, gross value.	Total.	Tolls paid for refining.	Freight.	Commissions and selling expenses.	
			Pounds.	Gross value.						
All establishments	40									$240,780,216
Establishments reporting gross and net values	29	$145,775,565	939,211,635	$119,503,347	$26,272,218	[1]$10,347,562	$4,458,851	$2,825,057	$1,447,680	135,428,003
Smelters, total	24	90,880,376	572,290,970	72,623,376	18,257,000	[1]9,127,967	4,417,458	2,773,413	1,421,254	81,752,409
Arizona	7	25,300,424	187,593,252	23,688,231	1,612,193	[1]2,538,443	1,086,673	873,267	404,737	22,761,981
Utah	5	9,150,100	39,834,080	5,001,201	4,148,899	[1]651,144	209,090	178,484	44,610	8,498,956
All other states[2]	12	56,429,852	344,863,638	43,933,944	12,495,908	[1]5,938,380	3,121,695	1,721,662	971,907	50,491,472
Smelters and refineries[3]	5	54,895,189	366,920,665	46,879,971	8,015,218	[1]1,219,595	41,393	51,644	26,426	53,675,594

[1] Includes $1,615,974 of deductions not reported in detail. This total was distributed as follows: Smelters, $515,842—Arizona, $173,766; Utah, $218,960; "all other states" $123,116—smelters and refineries, $1,100,132.
[2] Includes establishments distributed as follows: California, 2; Colorado, 2; Idaho, 1; Montana, 4; Oregon, 1; Virginia, 1; Washington, 1.
[3] Includes establishments distributed as follows: Colorado, 1; Michigan, 2; New York, 1; Tennessee, 1.

There were 24 of the 27 smelting establishments which reported gross and net values, and 5 of the 8 smelters and refineries, or a total of 29 out of the 40 establishments. The total products with a net value of $135,428,003 are the products against which deductions were reported, the deductions aggregating $10,347,562. Of this amount $1,615,974 was reported without any distribution being made between tolls paid for refining, freight, or commissions and selling expenses, hence it is included in the total amount of deductions but not in the segregated columns. If the deductions are all charged against the copper, it gives an average of 1.1 cents per pound of copper for the average expense of marketing the copper product of the smelters.

The detailed statistics for the copper smelting and refining industry at the census of 1905 are given in Table 17. The amount received for contract smelting and refining is given, but the ores thus treated are included in the quantities and values of the materials and products.

TABLE 17.—COPPER SMELTING AND REFINING—DETAILED SUMMARY, BY STATES AND TERRITORIES: 1905.

	United States.	Arizona.	California.	Michigan.	New Jersey.	Utah.	All other states.[1]

Wages	.....	$1,980	.....
Miscellaneous expenses	$897,876	$1,166,210	[1]23.0
Cost of materials used	$168,958,076	$144,195,163	17.2
Value of products	$185,826,839	$175,466,304	5.9

[1] Decrease.

Table 18 includes only active establishments. In addition there were 3 idle establishments reported at the census of 1905, located 1 in California, 1 in Colorado, and 1 in New Mexico, which reported capital investment and power equipment as follows:

TABLE 19.—*Lead smelting and refining—idle establishments: 1905.*

Number of establishments	3
Capital, total	$326,400
Land	$6,800
Buildings	$152,600
Machinery, tools, and implements	$167,000
Power owned:	
Number of establishments reporting	3
Total horsepower	965
Engines, steam—	
Number	5
Horsepower	665
Electric motors—	
Number	3
Horsepower	300

At the census of 1900 there were 3 idle establishments with a capital of $629,871, located 1 in Missouri, 1 in Nevada, and 1 in Utah.

The statistics compiled at the census of 1890 were not in conformity with the methods followed in compiling the statistics for manufactures for 1900 and 1905, and therefore can not be used for purposes of comparison, but Table 20 shows the totals for the lead smelting and refining works as reported at that census.

TABLE 20.—*Lead smelting and refining: 1890.*

Expenditures, total	$11,457,367
Wages	$4,228,634
Salaries	$510,716
Supplies and materials	$5,154,682
Rent, insurance, taxes, etc	$1,489,715
Contractors	$73,620
Number of employees:	
Office force	249
Foremen	173
Mechanics	354
Laborers	5,595
Boys	9
Average daily wages:	
Foremen	$3.98
Mechanics	$2.93
Laborers	$2.15
Boys	$0.50
Average days employed:	
Foremen	337
Mechanics	322
Laborers	307
Boys	336
Products:	
Refined lead (tons)	182,967
Fine copper in matte (pounds)	4,195,929
Stock:	
Base bullion (tons), January 1, 1889	1,474
Base bullion (tons), January 1, 1890	4,730
Refined lead (tons), January 1, 1889	12,058
Refined lead (tons), January 1, 1890	9,230

The lead product reported at the census of 1900, as compared with that of 1890, increased 60.7 per cent, and at the census of 1905 as compared with that of 1900, 33.2 per cent. On account of the different methods of treating the smelting industry prior to 1890, census figures comparable with those for 1900 and 1905 are not available, but the statistics of lead production, as compiled by the Geological Survey since 1873, are presented in Table 21.

TABLE 21.—*Production of refined lead in the United States: 1873 to 1904.*[1]

YEAR.	Total (tons).	Desilverized lead (tons).	Soft lead (tons).
1904	404,453	315,284	89,169
1903	378,518	295,074	83,444
1902	377,061	303,011	74,050
1901	381,688	323,790	57,898
1900	377,679	329,658	48,021
1899	304,392	263,826	40,566
1898	310,621	267,842	42,779
1897	291,036	247,483	43,553
1896	264,994	221,457	43,537
1895	241,882	201,992	39,890
1894	219,090	181,404	37,686
1893	229,333	196,820	32,513
1892	213,262	181,584	31,678
1891	202,406	171,009	31,397
1890	161,754	130,403	31,351
1889	182,967	153,709	29,258
1888	180,555	151,465	29,090
1887	160,700	135,552	25,148
1886	135,629	114,829	20,800
1885	129,412	107,437	21,975
1884	139,897	119,965	19,932

[1] United States Geological Survey, "Mineral Resources of the United States," 1904 and 1900.

TABLE 21.—*Production of refined lead in the United States: 1873 to 1904*—Continued.

YEAR.	Total (tons).	Desilverized lead (tons).	Soft lead (tons).
1883	143,957	122,157	21,800
1882	132,890	103,875	29,015
1881	117,085	86,315	30,770
1880	97,825	70,135	27,690
1879	92,780	64,650	28,130
1878	91,060	64,290	26,770
1877	81,900	50,748	31,152
1876	64,070	37,649	26,421
1875	59,640	34,909	24,731
1874	52,060	.....	.....
1873	42,540	20,159	22,381

The total production of refined lead as reported at the census of 1905 is 391,530 tons, or 12,923 tons less than the total shown for the calendar year 1904 in Table 21, due chiefly to the fact that the periods covered are not identical. The returns of the Geological Survey are for the calendar year, while the reports for the Census Office cover the fiscal year of the corporations reporting, which in only a few cases is the calendar year.

The production of refined lead, as shown by the Census reports, is given in Table 22 for the censuses of 1900 and 1905. To avoid disclosing individual operations, statistics by states can be shown only for Missouri in this and all other detailed tables.

TABLE 22.—*Lead smelting and refining—production of refined lead, by states: 1905 and 1900.*

STATE.	Census.	Total (tons).	Soft lead (tons).	Hard or antimonial lead (tons).	All other lead, including Dorébars (tons).
United States	1905	391,530	84,864	11,953	294,713
	1900	293,965	45,237	8,393	240,335
Missouri	1905	53,840	53,840	.....	.....
	1900	41,976	41,976	.....	.....

	[2] 1900	251,989	3,261	8,393	240,335

[1] Includes states as follows: California, Colorado, Idaho, Illinois, Iowa, Kansas, Montana, Nebraska, New Jersey, Pennsylvania, Texas, Utah, Washington, Wisconsin.

[2] Includes states as follows: California, Colorado, Idaho, Illinois, Iowa, Kansas, Montana, Nebraska, New Jersey, New Mexico, Texas, Utah, Virginia, Washington.

THE INDUSTRY, BY STATES.

Table 23 presents the general statistics by states for 1900 and 1905.

TABLE 23.—LEAD SMELTING AND REFINING—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
				Number.	Salaries.	Average number.	Wages.			
United States	1905	32	$63,822,810	524	$887,602	7,573	$5,374,691	$897,876	[1] $168,958,076	[1] $185,826,839
	1900	39	72,148,933	425	754,913	8,319	5,088,684	1,166,210	[1] 169,703,366	[1] 200,974,507
Missouri	1905	8	1,341,292	41	79,977	489	275,912	64,486	4,683,846	5,473,586
	1900	11	944,539	35	47,360	474	255,590	41,565	3,317,558	3,852,435
All other states	[2] 1905	24	62,481,518	483	807,625	7,084	5,098,779	833,390	164,274,230	180,353,253
	[3] 1900	28	71,204,394	390	707,553	7,845	4,833,094	1,124,645	166,385,808	197,122,072

[1] Includes a duplication in cost of materials and value of products of $1,036,848 for 1905 and of $25,508,203 for 1900. The latter amount represents intermediate products between the ore and the refined metal.

[2] Includes establishments distributed as follows: California, 1; Colorado, 7; Idaho, 1; Illinois, 3; Iowa, 1; Kansas, 1; Montana, 1; Nebraska, 1; New Jersey, 2; Pennsylvania, 1; Texas, 1; Utah, 1; Washington, 2; Wisconsin, 1.

[3] Includes establishments distributed as follows: California, 1; Colorado, 8; Idaho, 1; Illinois, 2; Iowa, 1; Kansas, 2; Montana, 3; Nebraska, 1; New Jersey, 2; New Mexico, 1; Texas, 1; Utah, 2; Virginia, 1; Washington, 2.

Table 24 presents the statistics for the establishments grouped according to location, east and west of the Mississippi river, for 1900 and 1905, with the respective per cents of increase.

TABLE 24.—LEAD SMELTING AND REFINING—COMPARATIVE SUMMARY OF ESTABLISHMENTS, BY LOCATION, EAST AND WEST OF THE MISSISSIPPI RIVER: 1905 AND 1900.

	TOTAL.		EAST OF THE MISSISSIPPI.		WEST OF THE MISSISSIPPI.		PER CENT OF INCREASE.

Arsenic, pounds	554,445	[3]		[3]	554,445	( )			

[1] Decrease.
[2] Includes a duplication in cost of materials and value of products of $1,036,848 for 1905, and $25,508,203 for 1900. The latter amount represents intermediate products between the ore and the refined metal.
[3] Not reported separately.

The decrease in the number of active establishments and in the capital invested, wage-earners employed, and general operating expense has all been in the West, the establishments located east of the Mississippi river showing an increase in all of these particulars. On account of the large duplication in cost of materials and value of products in the figures for 1900, which duplication represents the intermediate products of the smelting department in the case of establishments doing both smelting and refining, the detailed figures for materials and products are not in all cases comparable. Deducting the duplication of $1,036,848 for 1905, which all pertains to western establishments, and the duplication of $25,508,203 for 1900, of which amount $801,000 pertains to eastern smelters and the balance to western establishments, there is deduced a comparison of materials and products, as shown in Table 25.

TABLE 25.—LEAD SMELTING AND REFINING—COMPARATIVE SUMMARY OF MATERIALS AND PRODUCTS, NET COST AND VALUE, IN ESTABLISHMENTS, BY LOCATION, EAST AND WEST OF THE MISSISSIPPI RIVER: 1905 AND 1900.

	TOTAL.		EAST OF THE MISSISSIPPI.		WEST OF THE MISSISSIPPI.		PER CENT OF INCREASE.		
	1905	1900	1905	1900	1905	1900	Total.	East.	West.
Materials used, total cost	$167,921,228	$144,195,163	$43,522,255	$32,162,166	$124,398,973	$112,032,997	16.5	35.3	11.0
Products, aggregate value	184,789,991	175,466,304	46,933,641	38,191,943	137,856,350	137,274,361	5.3	22.9	0.4
Smelting	62,220,245	51,553,074	1,977,553	681,583	60,242,692	50,871,491	20.7	190.1	18.4
Refining and desilverizing	116,415,834	115,527,046	44,912,506	35,539,270	71,503,328	79,987,776	0.8	26.4	[1]10.6
All other products	6,153,912	8,386,184	43,582	1,971,090	6,110,330	6,415,094	[1]26.6	[1]97.8	[1]4.8

[1] Decrease.

In addition to the duplication before noted there is also the duplication arising from the refining of the product of the argentiferous smelters, when done by a separate refinery. In such cases the product of the smelters appears as material for a refinery, and materials and products are duplicated to this extent, but it is only where materials and products are included twice in the report for the same establishment that they are considered as duplications. The above comparison shows the greater increase in the eastern smelters.

The Missouri smelters handle nonargentiferous ores exclusively, and a comparison of the operating expenses for the censuses of 1890, 1900, and 1905 is presented in Table 26.

TABLE 26.—*Lead smelting and refining—statistics of Missouri smelters: 1890 to 1905.*

	1905	1900	1890[1]	Per cent of increase, 1900 to 1905.
Total expenses	$650,123	$530,693	$580,210	22.5
Salaries	$79,977	$47,360	$19,680	68.9
Wages	$275,912	$255,590	$206,541	8.0
Miscellaneous expenses, not including contract work	$53,552	$41,565	$166,632	28.8
Amount received for contract work	$10,934	$25,382	$3,182	[2]56.9
Cost of materials used, not including ore	$229,748	$160,796	$184,175	42.9
Quantity of ore treated (tons)	88,286	68,719	49,816	28.5
Lead produced (tons)	53,840	41,976	29,258	28.3
Oxide produced (tons)	5,645	5,165	1,250	9.3

[1] Includes the data for Illinois, Kansas, Missouri, Wisconsin.
[2] Decrease.

The average wage expense per ton of ore smelted was $3.13 for 1905, compared with $3.72 for 1900 and $4.15 for 1890.

MATERIALS USED.

Table 27 shows the quantities of ore and base bullion consumed by smelters and refineries as reported at the censuses of 1900 and 1905. The source of the base bullion, whether foreign or domestic, is shown, but the returns for the census of 1905 do not show the quantity of foreign ore consumed. In 1900 there were 284,914 tons of foreign ore and 1,667,545 tons of domestic.

TABLE 27.—*Lead smelting and refining—quantity of ore smelted and base bullion refined and desilverized, by states: 1905 and 1900.*

STATE.	Census.	Ore smelted (tons).	BASE BULLION REFINED AND DESILVERIZED.		
			Total (tons).	Domestic (tons).	Foreign (tons).
United States	1905	2,412,005	337,015	239,836	97,179
	1900	1,952,459	259,937	180,998	78,939
Missouri	1905	88,286	.....	.....	.....
	1900	68,719	.....	.....	.....
All other states	[1]1905	2,323,719	337,015	239,836	97,179
	[2]1900	1,883,740	259,937	180,998	78,939

[1] Includes states as follows: California, Colorado, Idaho, Illinois, Iowa, Kansas, Montana, Nebraska, New Jersey, Pennsylvania, Texas, Utah, Washington, Wisconsin.
[2] Includes states as follows: California, Colorado, Idaho, Illinois, Iowa, Kansas, Montana, Nebraska, New Jersey, New Mexico, Texas, Utah, Virginia, Washington.

The consumption of ore shows an increase of 459,546 tons, or 23.5 per cent, and base bullion purchased, an increase of 77,078 tons, or 29.7 per cent, the domestic base bullion increasing 58,838 tons, or 32.5 per cent, and foreign bullion 18,240 tons, or 23.1 per cent.

PRODUCTS.

Table 28 gives the quantity and the value of the different classes of products, and the number of establishments reporting each class for 1900 and 1905.

TABLE 28.—LEAD SMELTING AND REFINING—PRINCIPAL PRODUCTS, BY KIND, QUANTITY, AND VALUE, WITH NUMBER OF ESTABLISHMENTS REPORTING: 1905 AND 1900.

KIND.	Census.	Number of establishments reporting.	PRODUCTS.		
			Unit of measure.	Quantity.	Value.
Smelting nonargentiferous ores:					
Soft lead	1905	16	Pound	169,728,880	$7,324,869
	1900	17	Pound	90,473,286	3,801,242
Smelting argentiferous ores:					
Lead contents of base bullion	1905	12	Pound	449,935,104	13,757,268
	1900	[1]23	Pound	402,324,605	15,546,661
Silver	1905	12	Ounce fine	37,543,073	21,322,494
	1900	[1]23	Ounce fine	52,641,752	31,185,203
Gold	1905	12	Ounce fine	965,048	19,815,614
	1900	[1]22	Ounce fine	1,322,177	26,528,171
Copper contents of matte	1905	12	Pound	51,617,670	4,812,865
	1900	19	Pound	26,964,031	3,768,402
Refining and desilverizing:					
Hard or antimonial lead	1905	6	Pound	23,905,398	925,117
	1900	8	Pound	16,785,097	701,082
All other lead (including Doré bars)	1905	7	Pound	589,426,558	22,107,915
	1900	9	Pound	480,670,834	20,672,140
Doré bars and fine bars, silver	1905	7	Ounce fine	72,592,987	41,425,114
	1900	9	Ounce fine	70,420,917	42,143,703
Doré bars and fine bars, gold	1905	7	Ounce fine	2,574,549	52,994,536
	1900	9	Ounce fine	2,514,836	52,010,121

[1] Includes smelters combined with refineries and duplication of intermediate products between smelting and refining departments.

There were 16 establishments that engaged in smelting nonargentiferous ores in 1905 as compared with 17 in 1900, and 19 in smelting argentiferous ores in 1905 as compared with 23 in 1900. Seven of the 19 argentiferous smelters in 1905 did both smelting and refining, and hence are classed as refiners, making 12 establishments engaged in the smelting only of argentiferous ores.

A comparison of the lead, gold, and silver products, quantities and values, for 1900 and 1905, and the per cent of increase is shown in the following statement:

Lead smelting and refining—quantity and value of principal products, with per cent of increase: 1905 and 1900.

KIND.	PRODUCTS.				PER CENT OF INCREASE.	
	Quantity.		Value.			
	1905	1900	1905	1900	Quantity.	Value.
Total	.....	.....	$124,777,551	$119,328,288	.....	4.6
Lead, total (pounds)	783,060,836	587,929,217	30,357,901	25,174,464	33.2	20.6
Soft	169,728,880	90,473,286	7,324,869	3,801,242	87.6	92.7
Hard or antimonial	23,905,398	16,785,097	925,117	701,082	42.4	32.0
All other	589,426,558	480,670,834	22,107,915	20,672,140	22.6	[1]6.9
Gold and silver (ounces fine)	.....	.....	94,419,650	94,153,824	.....	0.3
Gold	2,574,549	2,514,836	52,994,536	52,010,121	2.4	1.9
Silver	72,592,987	70,420,917	41,425,114	42,143,703	3.1	[1]1.7

[1] Decrease.

The heavy increase in the consumption of dry ores by the copper smelters has been at the expense of the lead smelters and is shown in the relative decrease of the silver and gold products of this industry. The hard or antimonial lead and "all other" lead represents the lead product of the argentiferous smelters and the lead smelters handling dry ores.

The increase in the combined product of hard or antimonial lead and "all other" lead for 1900 and 1905 was 23.3 per cent, while the increase in the silver

and gold product, measured by quantities, was very small.

This marked change is not due in the case of the lead smelters to a falling off in the precious metal values of the argentiferous lead ores treated, nor in the case of the copper smelters to a general increase in the precious metal values of the copper ores handled, but it results from the large increase in the quantity of dry gold and silver ores handled by the latter.

Table 29 presents the quantities of the different varieties of products, for Missouri and "all other states," for 1900 and 1905.

TABLE 29.—LEAD SMELTING AND REFINING—PRINCIPAL PRODUCTS, BY KIND AND QUANTITY, AND BY STATES: 1905 AND 1900.

STATE.	Census.	SMELTING.						REFINING AND DESILVERIZING.			
		Nonargentiferous ores.		Argentiferous ores.				Hard or antimonial lead (pounds).	All other lead, including Doré bars (pounds).	Doré bars, contents of precious metals, and fine bars.	
		Soft lead (pounds).	Lead oxide (pounds).	Lead contents of base bullion (pounds).	Silver (ounces fine).	Gold (ounces fine).	Copper contents of matte (pounds).			Silver (ounces fine).	Gold (ounces fine).
United States	1905	169,728,890	11,289,399	449,935,104	37,543,073	965,048	51,617,670	23,905,398	589,426,558	72,592,987	2,574,549
	1900	90,473,286	10,329,804	402,324,605	52,641,752	1,322,177	26,964,031	16,785,097	480,670,834	70,420,917	2,514,836
Missouri	1905	107,680,403	11,289,399	.....	.....	.....	48,000	.....	.....	.....	.....
	1900	83,952,833	10,329,804	.....	.....	.....	.....	.....	.....	.....	.....
All other states	[1]1905	62,048,477	.....	449,935,104	37,543,073	965,048	51,569,670	23,905,398	589,426,558	72,592,987	2,574,549
	[2]1900	6,520,453	.....	402,324,605	52,641,752	1,322,177	26,964,031	16,785,097	480,670,834	70,420,917	2,514,836

[1] Includes states as follows: California, Colorado, Idaho, Illinois, Iowa, Kansas, Montana, Nebraska, New Jersey, Pennsylvania, Texas, Utah, Washington, Wisconsin.

[2] Includes states as follows: California, Colorado, Idaho, Illinois, Iowa, Kansas, Montana, Nebraska, New Jersey, New Mexico, Texas, Utah, Virginia, Washington.

The location of the dry gold and silver ores and cheap fuel have been the chief factors which have influenced the location of the lead smelters.

The Missouri smelters are the largest producers of soft lead. The product of the state increased 23,727,570 pounds in 1905 over 1900, or 28.3 per cent; its output constituting 63.4 per cent of the total product of 1905 as compared with 92.8 per cent in 1900. The large increase in the soft lead product of the Illinois and Kansas smelters operates to lower the proportional share of the Missouri smelters.

Missouri also manufactured the entire product of lead oxide reported at both censuses. While the bulk of the smelting of argentiferous ores centers in Colorado, Utah, Washington, Texas, and Montana, in the order named, the refining and desilverizing is located in California, Nebraska, New Jersey, Illinois, and Washington. Idaho is the largest producer of lead ores, outranking Utah, Colorado, and the soft lead states of the Mississippi valley, but its argentiferous lead ores are shipped to smelters in other states and a very small amount is smelted within the state.

PROCESS EMPLOYED—SMELTING, AND SMELTING AND REFINING.

Table 30 presents the statistics for all establishments for 1900 and 1905, segregated according to those doing smelting only and those doing smelting and refining—the latter including refining only—with the per cent of increase.

As before noted there is included in materials and products the duplication arising from the intermediate product between the ore and the refined metal being reported in certain cases by establishments doing both smelting and refining, this intermediate product appearing as product of the smelting department and as material for the refining department.

The group of establishments doing only smelting shows a large increase in capital, while the smelting and refining shows a decrease from 1900 to 1905. With respect to wage-earners there is a decrease in each group, with the larger proportional decrease in the smelting and refining group.

TABLE 30.—LEAD SMELTING AND REFINING—ESTABLISHMENTS CLASSIFIED ACCORDING TO PROCESS EMPLOYED, WITH PER CENT OF INCREASE: 1905 AND 1900.

[1] Decrease.
[2] Includes a duplication in cost of materials and value of products of $1,036,848 for 1905 and $25,508,203 for 1900. The latter amount represents intermediate products between the ore and the refined metal.
[3] Not reported separately.

If correction is made for the duplication due to intermediate products the comparative figures for materials and products are as given in Table 31.

TABLE 31.—LEAD SMELTING AND REFINING—COMPARATIVE SUMMARY OF MATERIALS AND PRODUCTS, NET COST AND VALUE, CLASSIFIED ACCORDING TO PROCESS EMPLOYED: 1905 AND 1900.

GROSS AND NET VALUES OF PRODUCTS.

In making the canvass for the census of 1905 inquiries were made as to the expense of marketing the product of the smelters, in order to show the gross and net values of the smelter products. This expense consists of tolls paid for refining, freight on bullion, matte, or other smelter product to the refining or desilverizing establishment, treating the smelter product, and commissions and selling expenses. In the prior tables the values of products have been net values. Table 32 presents the statistics bearing on gross and net values and the deductions reported.

TABLE 32.—LEAD SMELTING AND REFINING—ESTABLISHMENTS REPORTING GROSS AND NET VALUES OF PRODUCTS: 1905.

	Total.	SMELTERS ONLY.		Refineries and desilverizers, including smelters connected with refineries.

Freight	$212,351	.....	$185,925	$26,426
Commissions and selling expenses	$22,326	.....	$22,326	.....
All other establishments:				
Number	12	9	.....	3
Products	$37,216,873	$5,311,492	.....	$31,905,381

[1] Commissions and selling expenses reported by 4 smelting establishments—3 nonargentiferous and 1 argentiferous.
[2] Gross value: Copper contents of matte, $5,906,311; other products, $500. Net value: Copper contents of matte, $4,332,502; other products, $490.
[3] Gross value: Copper and copper contents of matte, $516,859: blue vitriol, $398,626. Net value: Copper and copper contents of matte, $475,963; blue vitriol, $381,787.

Of the 32 establishments there were 20 reporting gross and net values, 4 of these being nonargentiferous smelters, 12 argentiferous smelters, and 4 refineries or smelters and refineries. The gross value of the products charged with deductions was $62,086,584, against which the deductions were $7,078,796, leaving $55,007,788 as the net value of the same. The 20 establishments reporting deductions had products of a value of $93,602,178 not charged with deductions, and the remaining 12 establishments had products amounting to $37,216,873, making a total of $130,819,051 of products not charged with the expense of subsequent treatment. In the case of the few nonargentiferous smelters reporting deductions they are entirely for freight and selling expense. The bulk of the deductions pertain to the bullion and matte products of the argentiferous smelters. The lead contents of the base bullion product of the argentiferous smelters amounted to 449,935,104 pounds and the tolls paid for refining were $3,792,067 and freight to refineries $2,331,948.

The detailed statistics for the lead smelting and refining industry at the census of 1905 are shown in Table 33. The amount received for contract smelting and refining is given, but the ores thus treated are included in the quantities and values of the materials and products.

ZINC SMELTING.

The vigorous growth of the zinc smelting industry noted at the census of 1900 has continued, and the production of spelter, including sheet zinc, at the census of 1905 reached a total of 186,990 tons, as compared with 131,546 tons for 1900, 58,860 tons for 1890, and 23,239 tons for 1880. This shows an increase of 35,621 tons for the decade 1880 to 1890; 72,686 tons for the decade 1890 to 1900; and 55,444 tons for the five-year period 1900 to 1905.

The general comparative statistics for the industry are given in Table 34 for 1890, 1900, and 1905, with the per cent of increase. The statistics for 1890 in the table are taken from the Eleventh Census of mines and mining.

TABLE 34.—*Zinc smelting—comparative summary, with per cent of increase: 1890 to 1905.*

[1] Report on Mineral Industries, Eleventh Census.
[2] Not reported separately.
[3] Decrease.
[4] Value of products not reported.

Although the number of establishments is the same for 1905 as for 1900, the increase in capital invested, wage-earners, and materials and products indicate the steady growth of the industry. In addition to the active establishments shown, there were 3 idle establishments reported at the census of 1905, located 2 in Iowa and 1 in Pennsylvania, which reported capital investment and power equipment as shown in Table 35.

TABLE 35.—*Zinc smelting—idle establishments: 1905.*

Number of establishments	3
Capital, total	$386,000
Land	$131,600
Buildings	$216,600
Machinery, tools, and implements	$35,300
Cash and sundries	$2,500
Power, owned:	
Number of establishments reporting	3
Total horsepower	1,095
Engines, steam—	
Number	5
Horsepower	1,070
Water wheels—	
Number	1
Horsepower	25

In 1900 there were 2 idle establishments, in addition to the 31 active establishments, with a capital of $59,500, located 1 in Kansas and 1 in Virginia.

On account of the different methods of treating the smelting industry prior to 1890 Census figures comparable with those of 1900 and 1905 are not available, but the production of spelter as compiled by the Geological Survey since 1873 is presented in Table 36.

TABLE 36.—*Production of spelter in the United States: 1873 to 1904.* [1]

YEAR.	Quantity (tons).	YEAR.	Quantity (tons).
1904	186,702	1891	80,873
1903	159,219	1890	63,083
1902	156,927	1889	58,800
1901	140,822	1888	55,903
1900	123,886	1887	50,340
1899	129,051	1886	42,641
1898	115,399	1885	40,688
1897	99,980	1884	38,544
1896	81,499	1883	36,872
1895	89,686	1882	33,765
1894	75,328	1880	23,239
1893	78,832	1875	15,833
1892	87,260	1873	7,343

[1] United States Geological Survey, "Mineral Resources of the United States," 1904.

The total production of spelter, including sheet zinc made at the smelters, as reported at the census of 1905, was 186,990 tons, or 288 tons more than for the calendar year 1904 as shown in Table 36, due to the fact that the periods covered are not identical. The returns for the United States Geological Survey are for the calendar year, while the reports for the Census Office cover the fiscal year of the establishment reporting most nearly conforming to the calendar year 1904, and in a number of reports the fiscal year includes part of 1905.

THE INDUSTRY, BY STATES.

The general statistics, by states, for the censuses of 1900 and 1905, so far as they can be given, are shown in Table 37.

TABLE 37.—ZINC SMELTING—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
				Number.	Salaries.	Average number.	Wages.			
United States	1905	31	$23,701,586	354	$581,479	6,528	$3,856,466	$1,326,621	$17,028,418	$24,791,299
	1900	31	14,141,810	208	440,200	4,869	2,355,921	399,472	13,286,058	18,188,498

	[3] 1900	4	2,916,472	54	99,179	764	390,362	161,536	1,255,319	2,536,934

[1] Included in "all other states" in 1905.
[2] Includes establishments distributed as follows: Colorado, 2; New Jersey, 1; Pennsylvania, 3; Virginia, 1; West Virginia, 1; Wisconsin, 1.
[3] Includes establishments distributed as follows: New Jersey, 2; Virginia, 1; Wisconsin, 1.

The production of the Illinois and Missouri zinc smelters shows a decrease at the census of 1905 over that of 1900, and no production was reported from Indiana, but the output of the Kansas zinc smelters has nearly doubled since 1900, and Pennsylvania's output has more than doubled, though the detailed statistics for the latter state can not be shown and are included in "all other states."

Table 38 presents the statistics for establishments located east and west of the Mississippi river, for the censuses of 1900 and 1905, with per cent of increase.

TABLE 38.—ZINC SMELTING—COMPARATIVE SUMMARY OF ESTABLISHMENTS, BY LOCATION, EAST AND WEST OF THE MISSISSIPPI RIVER: 1905 AND 1900.

All other products	$5,580,440	$3,345,082	$4,346,171	$3,345,082	$1,234,269		66.8	29.9	

[1] Decrease.

In 1900, although the quantity of zinc made by the western establishments exceeded the zinc output of the eastern plants, the total value of the products of the eastern plants was largely in excess, the latter producing $3,143,370 of zinc oxide and sulphuric acid besides other products, in addition to spelter and sheet zinc products; that is, in 1900 the output of the western smelters was all in the form of spelter; while of the eastern establishments only 67.8 per cent of the total products was spelter and sheet zinc.

For 1905 the western establishments show a production of 257,632,103 pounds of zinc (spelter and sheet zinc), of a value of $12,823,354, an increase of 77.4 per cent in quantity and 64.4 per cent in value over 1900, and in addition zinc oxide, sulphuric acid, and other products of a value of $1,234,269; whereas the

eastern establishments show a slight decrease in zinc metal product for 1905 over 1900, with an increase in other products, the total products of the eastern smelters showing a small increase of 3.3 per cent, as compared with an increase of 80.2 per cent for the western establishments. For 1905 zinc metal constituted 59.5 per cent of the total products of the eastern smelters (67.8 per cent in 1900) and 91.2 per cent of the product of the western.

The capital invested in the entire industry shows a very heavy increase, and, as at the census of 1900, is in part due to improvements in appliances and in part to the development of industries collateral to zinc smelting, viz, the manufacture of zinc oxide, sulphuric acid, and the rolling of zinc. The production of rolled sheet zinc by zinc smelting establishments has increased from 9,389 tons at the census of 1890 to 17,723 tons at the census of 1900 and to 24,346 tons for 1905, an increase of 37.4 per cent for 1905 as compared with 1900. The production of zinc oxide by smelting establishments increased from 37,557 tons for 1900 to 58,743 tons for 1905, or 56.4 per cent; and sulphuric acid from 58,828 tons for 1900 to 77,305 tons for 1905, or 31.4 per cent.

In the report for the zinc smelting industry for the Twelfth Census a presentation was made of the statistics by two groups of states, one group including the works of the Mississippi valley states, which are dependent almost exclusively upon the ores mined in the Mississippi valley, and purchase their ores in the open market, and the other group including the works of the states which control nearly the whole of their own ore supply. The first group then included the works of Illinois, Indiana, Kansas, Missouri, and Wisconsin, and the latter, the works of Pennsylvania, New Jersey, and Virginia, all eastern states.

Table 39 presents corresponding statistics for 1905 in comparison with those of 1900, and gives the per cent of increase.

TABLE 39.—ZINC SMELTING—COMPARATIVE SUMMARY OF ESTABLISHMENTS ARRANGED ACCORDING TO LOCATION: 1905 AND 1900.

[1] Includes states as follows: 1905—New Jersey, Pennsylvania, Virginia, West Virginia. 1900—New Jersey, Pennsylvania, Virginia.
[2] Includes states as follows: 1905—Colorado, Illinois, Kansas, Missouri, Wisconsin. 1900—Illinois, Indiana, Kansas, Missouri, Wisconsin.
[3] Decrease.

The state of Colorado appears as a producer for 1905 and has been included in the first group, though the ores handled by the Colorado smelters are not Mississippi valley ores. The table therefore presents the statistics grouped to show the western establishments, which with one exception purchased their ores, and the eastern establishments, which control nearly the whole of their own supply.

There were 4 establishments which treated exclusively ores produced from their own mines, valued in all at $1,539,106 and located 1 in Missouri, 1 in New Jersey, and 2 in Pennsylvania. All other establishments operated on purchased ores.

The establishments purchasing their ores report the price paid for ore in the open market, while the establishments smelting ores produced by their own mines necessarily have to report an estimated cost for the ore at the smelter. The ores handled by the Colorado smelters are low grade zinc ores carrying values in lead and the precious metals, and are not in the same class with the rich zinc ores of the Mississippi valley. The average cost price paid by the Colorado smelters for ores approximates nearer to that of the eastern group than to that of the Mississippi valley smelters. The average cost per ton of the ores purchased by the Mississippi valley smelters for 1905 was $28.35 per ton as compared with an average cost of $33.67 for 1900, whereas the average cost of the ores used by the eastern group for 1905 was $5.82 per ton as against $5.44 per ton for 1900. At the census of 1900, the price of zinc ore in the Mississippi valley district was subject to wide fluctuations, zinc ore of standard quality in the bin at the mines reaching $55 per ton, and the average was abnormally high.

PRODUCTS.

Table 40 shows in detail the specific products of the zinc smelters for the United States, for 1900 and 1905.

TABLE 40.—*Zinc smelting—products, by kind, quantity, and value: 1905 and 1900.*

KIND.	1905	1900	Per cent of increase.
Total value	$24,791,299	$18,188,498	36.3
Spelter—			
Pounds	325,287,010	227,646,314	42.9
Value	$16,379,383	$12,348,036	32.6
Sheet zinc—			
Pounds	48,692,068	35,445,374	37.4
Value	$2,831,476	$2,495,380	13.5
Zinc oxide—			
Pounds	117,485,861	75,114,904	56.4
Value	$4,330,394	$2,718,700	59.3
Sulphuric acid—			
Pounds	154,609,036	117,655,214	31.4
Value	$576,060	$424,670	35.6
All other products	$673,986	$201,712	234.1

Between 1900 and 1905 the total production of zinc metal—spelter and sheet zinc—increased 110,887,390 pounds, or 42.1 per cent.

Kansas, which stood second at the census of 1890, was easily first both for 1900 and 1905. Its spelter product for 1900 was 109,031,632 pounds, or 41.4 per cent of the total spelter and sheet zinc product, and for 1905 its spelter and sheet zinc product was 221,638,884 pounds, or 59.3 per cent of the total. Illinois was second at both censuses, with 91,517,175 pounds of spelter and sheet zinc, or 34.8 per cent of the total product for 1900, and 93,419,339 pounds, or 25 per cent, for 1905; Missouri was third in both cases, with 36,213,583 pounds of spelter, or 13.8 per cent, for 1900, and 24,249,219 pounds of spelter, or 6.5 per cent, for 1905; and Pennsylvania fourth, with 3.6 per cent in 1900 and 4.1 per cent for 1905. Colorado and West Virginia appear as producers for the first time for 1905.

The use of natural gas as fuel was confined, at the census of 1905, to smelters in Kansas, and 9 plants reported natural gas used as fuel; 6 using gas from wells operated by the same owner, and 4 using purchased gas.

The following statement shows the fuel expense of the Kansas establishments:

CLASS OF FUEL USED.	Cost.
Total	$507,930
Natural gas, total	244,206
From wells operated by same owner	163,487
Purchased	80,719
Other fuel	263,724

In only 2 cases was natural gas alone used, 7 of the establishments using natural gas also using other fuel. Other fuel was used entirely by 2 smelters in the state.

The values reported for the products are the net values. The statistics with respect to amounts paid for freight and commissions and selling expenses are too incomplete to permit of any general deductions as to gross value of products. Of the 31 establishments, 8 reported freight on product to the amount of $197,315, and commissions and selling expenses to the amount of $38,452 on 133,597,263 pounds of spelter products of a net value of $6,724,034, or a gross value of $6,959,801. But 3 of these 8 establishments reported deductions on value of product for freight only, 1 a deduction for commissions and selling expenses only, and 4 deductions on account of freight and commissions and selling expenses. The 4 establishments reporting deductions for both freight and commissions and selling expenses were located 3 in Kansas and 1 in Missouri, and the total quantity of spelter product was 62,338,520 pounds, of a value per New York and St. Louis quotations of $3,072,469 and a net value of $2,967,619. The deductions were $81,040 for freight and $23,810 for commissions and selling expenses. The average gross value per pound, or value per New York and St. Louis quotations, was therefore 4.93 cents in the case of these 4 establishments; deductions for freight, 0.13 cent; for commissions and selling expenses, 0.04 cent, and net value, 4.76 cents.

Table 41 gives the detailed statistics for the industry at the census of 1905.

TABLE 41.—ZINC SMELTING—DETAILED SUMMARY, BY STATES: 1905.

	United States.	Illinois.	Kansas.	Missouri.	All other states.[1]

AGRICULTURAL IMPLEMENTS

AGRICULTURAL IMPLEMENTS.

The statistics of the manufacture of agricultural implements extend over half a century. They include the number and value of implements used for tilling the soil, sowing or planting the seed, harvesting, and preparing the crop for the market.

The importance of this industry is shown by the value of farm implements and machinery in use on the farms of the United States which in 1904 reached the sum of $844,989,863,[1] a gain of nearly $100,000,000 since 1900. The invention and perfection of machinery for use in connection with agriculture have revolutionized farming in the United States, and thus have exercised a far-reaching influence upon the economic conditions of the nation. Moreover, a large proportion of the labor-saving devices in use in the year 1905 upon farms in all parts of the globe were of American design and manufacture. But in spite of the wide extent of its market, the area of significant product within the United States is relatively small.

At the outset the industry was widely distributed in small shops over the country. The implements used were of simple construction, and their manufacture required little capital. With the progress in agriculture the demand grew for labor-saving devices. The increased cost of producing such machinery required increased capital, and to make the industry pay under present conditions, extensive and particularly expensive exploitation has been necessary. Indeed, the requirement for a large and increasing proportion of capital to product is now a marked characteristic of the industry.

The manufacture of agricultural implements is so closely allied to that of foundry and machine shop products that some establishments classified as "agricultural implements" at one census so change the character of their products as to come entirely or principally under "foundry and machine shop products" at a succeeding census, and thus drop out of the class in which they had been previously included. Such changes should be considered in comparing the statistics for the different censuses.

Table 1 presents the leading facts of the industry for each census from 1850 to 1905.

[1] Bureau of the Census, Report on Wealth, Debt, and Taxation, page 37.

TABLE 1.—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1850 TO 1905.

	CENSUS.							PER CENT OF INCREASE.

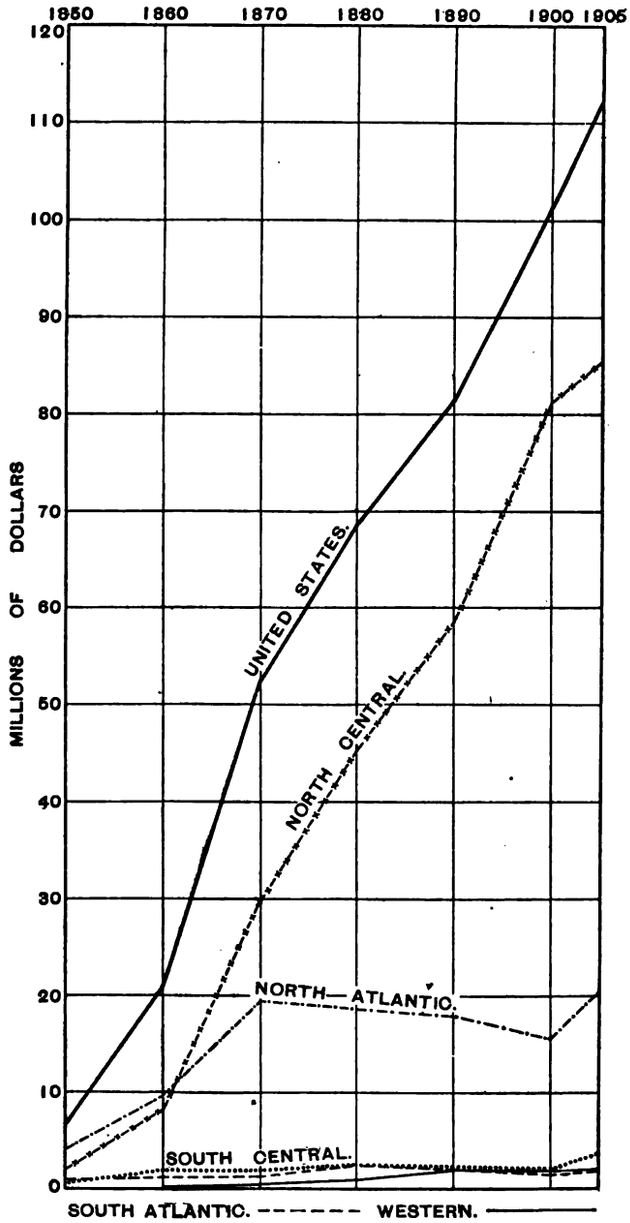
[1] Exclusive of the statistics of 93 establishments engaged primarily in the manufacture of other products. These establishments made agricultural implements to the value of $1,349,679.
[2] Decrease.
[3] Includes proprietors and firm members, with their salaries; number only reported in 1905 and 1900, but not included in this table.
[4] Not reported separately.
[5] Less than one-tenth of 1 per cent.
[6] Not reported.

The number of establishments has steadily decreased since 1860 until in 1905 there were less than half the number reported in 1850. To some extent this reduction is accounted for by the changes in classification, but a more important reason is undoubtedly the absorption of small establishments by large ones.

DIAGRAM 1.—*Comparative growth of the value of products, by geographic divisions: 1850 to 1905.*



With increased transportation facilities which bring the products of the great factories within easy reach of the farmer, many small shops which were formerly equal to supplying all local demands, have been either driven out of business or absorbed by larger establishments.

Coincident with the decrease in establishments there has been a steady increase in capital. Between 1850 and 1905 capital increased over fiftyfold. This increase is explained in part by the different methods of reporting capital employed at various censuses. Live capital—cash on hand, bills receivable, material and stock on hand, etc.—was first reported at the census of 1890. In all discussion of capital this fact should not be overlooked.

The decrease in the number of establishments and the increase in the capital invested, number of persons employed, and value of products indicate a concentration of the industry.

The centralizing tendency is further illustrated by the fact that the average capital invested and the average value of products per establishment increased from $2,674 and $5,133, respectively, at the census of 1850, to $303,612 and $172,850 at the census of 1905.

It is probable that the tendency shown toward increasing cost of materials is in part the result of change in the character of the principal material, rather than an increase in quantity. Wood was superseded by iron, and that in turn by steel. Furthermore, prices of the same material fluctuated from year to year, so that only the most general deductions can be made from the returns for cost of materials.

Value of products showed no change commensurate with those recorded in number of establishments. The value of products of the industry in 1905 was approximately sixteen times that of 1850. In the last thirty-five years the value of products has increased moderately but steadily. From 1900 to 1905, computed on the decade basis, the percentage of increase was slightly less than during the previous decade. It must be remembered, however, that the value of products in many industries has become so large that a small percentage often represents a great absolute increase.

The current expenditure per dollar of product—that is, salaries, wages, miscellaneous expenses, and cost of materials—has increased from 79 cents in 1890 to 85 cents in 1900 and 86 cents in 1905. Prior to 1890 the only items of current expenditures reported separately were wages and material. The amount thus expended per dollar of product was singularly uniform throughout the thirty years—67 cents in 1850, 62 cents in 1860, 65 cents in 1870, and 68 cents in 1880.

The following tabular statement shows the average value of products per establishment from 1850 to 1905:

CENSUS.	AVERAGE VALUE OF PRODUCTS PER ESTABLISHMENT.	
	Amount.	Per cent of increase.
1905	$172,850.84	22.1
1900	141,548.85	58.5
1890	89,309.51	152.8
1880	35,327.06	40.9
1870	25,080.38	154.8
1860	9,844.95	91.8
1850	5,133.24	.....

The industry by geographic divisions.—The distribution of the returns by geographic divisions of states brings out in a striking way the localization of the industry; this is shown in Table 2.

TABLE 2.—PER CENT DISTRIBUTION OF ESTABLISHMENTS, CAPITAL, AND VALUE OF PRODUCTS, WITH PER CENT OF INCREASE, BY GEOGRAPHIC DIVISIONS: 1905 AND 1900.

DIVISION.	ESTABLISHMENTS.			CAPITAL.			VALUE OF PRODUCTS.		
	Per cent of total.		Per cent of increase.	Per cent of total.		Per cent of increase.	Per cent of total.		Per cent of increase.
	1905	1900		1905	1900		1905	1900	
United States	100.0	100.0	[1] 9.4	100.0	100.0	24.8	100.0	100.0	10.7
North Atlantic	26.4	29.1	[1] 17.8	15.9	16.9	17.3	17.9	15.3	30.0
South Atlantic	7.2	5.7	14.6	0.7	0.7	20.8	1.5	1.2	33.3
North Central	57.6	57.6	[1] 9.5	80.6	79.7	26.2	76.1	80.1	5.2
South Central	4.3	4.1	[1] 3.4	1.5	1.4	31.7	2.9	1.9	69.3
Western	4.5	3.5	16.0	1.3	1.3	24.3	1.6	1.5	15.9

[1] Decrease.

The predominance of the North Central division in both 1900 and 1905 is very marked. The only division which in any degree competes with it is the North Atlantic. The latter, although it did not contribute one-fourth as much to the total value of product, increased from 1900 to 1905 at a rate about six times that of the North Central division. The North Atlantic and the South Central divisions gained slightly in their proportion of products, at the expense of the leading group.

The industry, by states.—Centralization is further emphasized when the contribution of each state to the total is seen. Table 3 is a comparative summary, by states and geographic divisions, for 1900 and 1905.

TABLE 3.—COMPARATIVE SUMMARY, BY STATES AND GEOGRAPHIC DIVISIONS: 1905 AND 1900.

Of the 37 states engaged in the manufacture of agricultural implements in 1905, 23 have reported manufactures at each of the seven censuses since 1850, and 4 others—California, Kansas, Minnesota, and Texas—since 1860. In the 10 remaining states the industry has maintained an irregular existence.

In 1880 only 12 states reported products valued at over $1,000,000 each. All of these except Massachusetts and Missouri have continued in the same class, and 4—Indiana, Michigan, Wisconsin, and Pennsylvania—within twenty-five years have raised their contribution beyond the $5,000,000 mark. New York has been prominent at every census since 1850, but after 1860 it ceased to be preeminent. In 1905, however, New York reported a gain of $2,508,637 coincident with Illinois' loss of $3,621,344.

In 1905, 24 states having products valued at more than $100,000, contributed 99.6 per cent of the total value of products; 6, having products valued at between $1,000,000 and $5,000,000, 10.1 per cent; and 7, whose products passed the $5,000,000 mark, 85.9 per cent. Of the last 7, Illinois, New York, and Ohio contributed 57.5 per cent, and Illinois alone 34.3 to the total output.

From Map 1 it will be observed that with the exception of California and Georgia the states reporting in 1905 a product valued at less than $5,000,000 but more than $1,000,000 border on the states reporting highest production, bounding these on the south and west. Georgia has passed the $1,000,000 mark since

1900, having become a center for the South as California became for the West.

In addition to a decrease in the value of products in two of the leading states—Ohio and Illinois—there has been a decrease since 1900 in Maine, New Hampshire, and Nebraska. These last states, however, report a comparatively insignificant output.

Rank of the three states leading in value of products in 1905: 1850 to 1905.

STATE.	1905	1900	1890	1880	1870	1860	1850
Illinois	1	1	1	2	3	3	4
New York	2	3	3	3	2	1	1
Ohio	3	2	2	1	1	2	5

MAP 1.—STATES HAVING PRODUCTS VALUED AT $100,000 AND OVER: 1905.

MAP 2.—STATES HAVING PRODUCTS VALUED AT $100,000 AND OVER: 1900.

The three states which led in 1860—New York, Ohio, and Illinois—were still the largest producers in 1905. They have each in turn held the lead, but Illinois outstripped Ohio in 1890, and made such rapid strides that it now far outdistances all others in value of products. The central location of Illinois and its proximity to the rich prairie farms of the central West is probably the primary cause of its preeminence.

It is unlikely that the decrease reported in 1905 in Illinois is more than temporary, since the decrease of $3,621,344 in value of products between 1900 and 1905 is due primarily to the fact that many of the largest plants had an unused production, or "carryover," at the close of the season of 1903 almost twice as large as that of any other year in their history. This resulted in a great decrease in production in 1904, the year covered by the census figures.

New centers of manufacture have appeared since 1900 in Iowa, Kansas, Minnesota, and Tennessee. The greatest advance has been in Kansas, where the value of products has increased more than twentyfold. In Iowa, the value of products has increased 78.4 per cent; in Minnesota, 63.6 per cent; and in Tennessee, 65.9 per cent.

The industry in cities.—In the report upon this industry at the census of 1900 a table was presented summarizing the returns for the cities in which this industry was an important factor. Table 4 presents the main statistics of the industry, as reported at the census of 1905, in cities of 20,000 population or over. The remarkable consolidation which has been in progress renders it necessary to include several of the cities shown in 1900 with "all other cities" in 1905.

TABLE 4.—SUMMARY FOR CITIES HAVING A POPULATION IN 1900 OF 20,000 OR OVER: 1905.

CITY.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.

York, Pa	5	1,475,441	76	71,414	809	318,953	116,328	637,245	1,263,635
All other cities[2]	85	54,773,557	1,822	1,801,781	15,381	8,315,207	2,243,000	15,048,378	32,876,741

[1] Population less than 20,000 in 1900, but the city is included in this table on account of its importance in the industry.

[2] Includes establishments distributed as follows: Akron, Ohio, 1; Albany, N. Y., 1; Anderson, Ind., 1; Atlanta, Ga., 1; Auburn, N. Y., 4; Bay City, Mich., 2; Binghamton, N. Y., 1; Boston, Mass., 1; Buffalo, N. Y., 1; Cedar Rapids, Iowa, 1; Chattanooga, Tenn., 2; Chicago, Ill., 6; Cleveland, Ohio, 1; Columbus, Ohio, 3; Council Bluffs, Iowa, 2; Dallas, Tex., 2; Denver, Colo., 1; Duluth, Minn., 1; East St. Louis, Ill., 1; Elmira, N. Y., 1; Harrisburg, Pa., 1; Jackson, Mich., 2; Joliet, Ill., 2; Kalamazoo, Mich., 2; Kansas City, Kans., 1; Los Angeles, Cal., 2; Louisville, Ky., 3; Macon, Ga., 1; Milwaukee, Wis., 4; New York, N. Y., 1; Oakland, Cal., 1; Omaha, Nebr., 1; Petersburg, Va., 1; Philadelphia, Pa., 2; Portland, Me., 1; Poughkeepsie, N. Y., 2; Richmond, Va., 2; Saginaw, Mich., 1; St. Joseph, Mo., 1; St. Louis, Mo., 2; St. Paul, Minn., 2; Salem, Mass., 1; San Francisco, Cal., 1; Springfield, Ill., 2; Syracuse, N. Y., 2; Toledo, Ohio, 2; Topeka, Kans., 1; Trenton, N. J., 2; Utica, N. Y., 2; Worcester, Mass., 2; Zanesville, Ohio, 1.

Of the establishments reported at the census of 1905, 26.5 per cent were located in the above cities. These plants returned 58.2 per cent of the entire capital invested in the industry and 56.9 per cent of the total value of products. The average capital per establishment for these cities was $665,928, and the average value of products was $370,857, while for all agricultural work outside of these cities the average capital and the average value of products per establishment was $172,691 and $101,302, respectively.

Chicago ranked first, but it has been included in "all other cities" in order not to disclose individual operations. Auburn, N. Y.; Columbus, Ohio; Louisville, Ky.; and Milwaukee, Wis., have also been so included for the same reason. The preeminence of Chicago is due chiefly to the extensive manufacture of harvesting machines, in which it leads all cities of the world. It also produced 69.4 per cent of the grain harvesters, 67.5 per cent of the headers and binders, 61.5 per cent of the mowers, 58.8 per cent of the reapers, 20.7 per cent of the corn harvesters, and 46.2 per cent of the horse hayrakes manufactured in the United States.

Although the population of Moline in 1900 was less than 20,000, the city is included in Table 4 on account of its importance in the industry, in which it ranks second. By far the greater value of its manufactures of agricultural implements was in implements of cultivation, viz, $5,945,108, or 71.2 per cent of the total value of all agricultural implements manufactured in the city.

Products.—Illinois leads in the production of most of the principal agricultural implements, some of the notable exceptions being horse hayforks, scythes, and thrashers. Of the first, Ohio contributes almost the

whole product, but in the manufacture of scythes Maine leads, followed by New York. The scythe, in fact, appears to be a distinctively Eastern product, being contributed in 1905, entirely by Maine, Connecticut, Vermont, New York, and New Hampshire. Iowa, which had a small product in 1900, reported none in 1905. The manufacture of thrashers centers in Michigan and Wisconsin, which together contributed about one-third the total number, but in 1905 the former reported an increasing and the latter a decreasing product.

Table 5 shows by states the number and kind of the principal agricultural implements reported at the census of 1905.

The total value of products, classified according to kind, is shown by states in Table 6.

TABLE 5.—NUMBER AND KIND OF PRINCIPAL AGRICULTURAL IMPLEMENTS MANUFACTURED, BY STATES: 1905.

45254—MFG 1905—PT 4—08——11

Implements of cultivation and harvesting, which together form more than one-half of the total value of products, are by far the most important classes, and are thus obviously the staple articles at the present time in this industry. It is of interest therefore to analyze the geographic location of these products. Seven states, all except Kentucky bordering the Great Lakes, reported approximately four-fifths of the value of implements of cultivation, and four—Illinois, New York, Ohio, and Wisconsin—nine-tenths of the value of harvesting implements. These values combined represent nearly 50 per cent of the total value of products. Unfortunately no comparison with 1900 is possible as this segregation was not made at that census.

It is from harvesting implements that Illinois derives supremacy in the industry, although this state also leads in value of products of implements of cultivation. New York and Illinois produced 73.6 per cent of the total value of harvesting implements manufactured. The preponderance of the value of these implements in the two leading states is noteworthy. It was the large value of this class of products in New York which enabled that state to outrank Ohio, since Ohio surpassed New York in the value of every other class of implements produced.

In value of implements of cultivation Indiana is second, closely followed by Ohio and New York. Kentucky, Michigan, and Wisconsin also passed the million dollar mark.

Table 7 compares the number and kind of implements manufactured as reported at each census from 1870 to 1905.

TABLE 7.—*Comparative summary—number and kind of agricultural implements manufactured: 1870 to 1905.*

[1] Harvesters of all kinds, not reported separately.
[2] Hay, manure, and spading forks, hand; not reported separately.
[3] Not reported separately.

General comparisons only are possible with the reports previous to 1900, owing to the difference in the schedules used before and since that census. The heads and subheads in the table are those of the schedule of inquiry for the census of 1905, and are almost identical with those of the 1900 schedule. For these years, therefore, a fair comparison can be made. At the three earlier censuses, however, the form varied materially and was much less comprehensive. Articles were put under one head which in the later censuses came under two or more heads, and some implements, manufactured only on a small scale, were left out altogether. Moreover at the later censuses there was naturally a greater variety of implements. Comparison of these earlier censuses with the later ones is, therefore, often misleading.

Horse corn planters increased steadily from 1890 to 1905, while the number of hand corn planters advanced from 1870 to 1900 and then declined. Of implements classed as seeders and planters, bean planters, cotton

planters, and manure spreaders have made the most marked gains since 1900, and of implements of cultivation, beet cultivators, celery hillers, markers and furrowers, steam and disk plows, and rollers, the greatest proportional increase. Disk harrows show an increase over 1900, while all other varieties show a decline.

The advance of over 54,000 dozens since 1900 in the number of hoes manufactured, indicates that no labor-saving device has yet been invented to supplant this simple and useful instrument.

The more important harvesting implements show a decrease in number. The falling off in harvesters and mowers, however, should not be interpreted as indicating a decline in the use of such implements, for a greater number of improved harvesting machines are in use to-day than ever before. The decrease in number manufactured may be accounted for, in part, by the fact that important manufacturers in Illinois and Ohio reported a greater "carryover" from the year 1903 than ever before. Also most of the large farms are now supplied with elaborate labor-saving devices, and as these are standardized so that when repair is needed the worn-out part may be easily replaced, new machines are not required for a long period of time.

The output of scythes has decreased steadily since 1880. Except in very rough and hilly regions, the scythe has been displaced by mowing machines, which require less labor. Mechanical motive power has been successfully adapted to use in mowing machines and the auto-mower is now a frequent sight in city parks.

Table 8 shows the number of establishments reporting each kind of implement with the number of each kind manufactured at the census of 1905.

Windmills	4	2,009

The tendency of establishments toward specialization is shown by an increase in the numbers of certain kinds of implements manufactured with a corresponding decrease in number of establishments reporting.

This was the case in connection with the following implements: Horse corn-planters, small and wheeled cultivators, disk harrows, shovel and walking plows, rollers, horse hayforks, hay loaders, hayrakes, and reapers.

The fourfold increase in the number of mowers and reapers combined is particularly marked when it is considered that the same number of establishments manufactured these in both years.

Attention is called to the list of implements enumerated under the heading "miscellaneous." Some of them are semiagricultural and not closely connected with the tilling of the soil, but are included because made in establishments manufacturing agricultural implements as their principal product.

All the foregoing statistics refer to establishments engaged exclusively or primarily in the manufacture of agricultural implements. The extent to which agricultural implements were manufactured as a minor product in connection with other industries is shown in Table 9.

TABLE 9.—INDUSTRIES MANUFACTURING AGRICULTURAL IMPLEMENTS AS A MINOR PRODUCT, WITH NUMBER OF ESTABLISHMENTS AND VALUE OF SUCH PRODUCTS, BY KINDS: 1905.

INDUSTRY.	Number of establishments.	VALUE OF PRODUCTS.						
		Total.	Seeders and planters.	Implements of cultivation.	Harvesting implements.	Seed separators.	All other agricultural implements and parts.	Amount received for repair work, etc.
Aggregate	741	$113,357,023	$11,450,958	$30,889,085	$31,030,843	$7,012,698	$30,961,391	$2,012,048
Agricultural implements	648	112,007,344	11,225,122	30,607,960	30,862,435	6,639,883	30,703,648	1,968,296
Industries otherwise classified	93	1,349,679	225,836	281,125	168,408	372,815	257,743	43,752
Foundry and machine shop products	54	823,412	123,804	216,917	48,945	207,561	204,621	21,564
Carriages and wagons	24	308,569	63,332	59,858	6,740	143,129	15,762	19,748
Lumber, planing mill products	5	53,748	1,000	.....	31,823	9,025	9,560	2,340
All other[1]	10	163,950	37,700	4,350	80,900	13,100	27,800	100

[1] Includes establishments distributed as follows: Cordage and twine, 1; dairymen's, poulterers', and apiarists' supplies, 2; galvanizing, 2; iron and steel forgings, 1; steam fittings and heating apparatus, 1; structural ironwork, 1; wood, turned and carved, 1; woodenware, not elsewhere specified, 1.

In view of the close relation between foundry and machine shop products and agricultural implements, it is but natural to find in that industry the greatest number of plants manufacturing agricultural implements as a minor product and the greatest value of this product.

The value of agricultural implements manufactured as a minor product by establishments in other industries forms but a small part of the aggregate value. Seed separators are in value the most important agricultural implements made by such establishments.

The 741 establishments engaged in the manufacture of agricultural implements, either as a principal or a subsidiary product, with their total value of products of $113,357,023, represent the actual extent of this manufacture in the United States during the calendar year 1904, so far as can be ascertained from the various schedules returned.

In addition to the 648 establishments reported at the census of 1905 as actively engaged in the manufacture of agricultural implements as a principal product, 8 idle establishments were reported, with a capital of $242,400. These idle establishments embrace plants that were once in operation but not operated during the census year.

Table 10 shows the number of establishments producing agricultural implements as a subsidiary product and the value of such products distributed by states.

TABLE 10.—*Establishments manufacturing agricultural implements as a minor product, and value of such products, by states: 1905.*

New York	7	54,119
North Carolina	3	5,375
Ohio	8	289,181
Pennsylvania	5	136,034
South Carolina	4	3,232
Vermont	4	16,900
Wisconsin	9	278,260
All other states[1]	11	74,164

[1] Includes establishments distributed as follows: Arkansas, 1; Connecticut, 1; Georgia, 1; Iowa, 1; Kansas, 1; Massachusetts, 1; Mississippi, 1; Texas, 1; Virginia, 2; Washington, 1.

These 93 plants, which were scattered over 24 states, do not cover all establishments in which a small quantity of agricultural implements or parts were produced, but only those which have separately reported finished implements in commercial quantities.

Of the states, California had by far the greatest number of plants; but the average value of product per establishment was only $1,503. Wisconsin ranked second in number of establishments, with an average value of product of $30,918. Ohio stood third in number of plants, but first in value of products. In

value of products, Wisconsin, Indiana, Illinois, and Pennsylvania followed in the order named.

Power.—Table 11 shows the different kinds of power employed by agricultural implement manufacturers at the censuses of 1900 and 1905.

TABLE 11.—*Power—comparative summary, with per cent each kind is of the total: 1905 and 1900.*

	1905		1900	
	Amount.	Per cent of total.	Amount.	Per cent of total.
Number of establishments reporting power	589	.....	595	.....
Total horsepower	106,623	100.0	77,189	100.0
Owned:				
Engines—				
Steam—				
Number	698	.....	678	.....
Horsepower	75,018	70.4	61,147	79.2
Gas and gasoline—				
Number	165	.....	75	.....
Horsepower	2,360	2.2	1,055	1.4

Electric motors—				
Number	182	.....	(1)	.....
Horsepower	3,828	3.6	1,100	1.4
Other kind, horsepower	75	0.1	266	0.3
Furnished to other establishments, horsepower	751	.....	338	.....

[1] Not reported.
[2] Less than one-tenth of 1 per cent.

The total horsepower used increased 38.1 per cent between 1900 and 1905. To this increase steam engines and electric motors were the largest contributers. The horsepower of the latter in 1905 was between two and three times as great as in 1900. Gas and gasoline engines, although they have more than doubled in number and horsepower, still form a very small proportion of the total. The only decreases reported are those for water wheels and "other kind" of rented power, 7 and 71.8 per cent, respectively.

Patents in relation to agricultural implements.—The following is a list of patents granted to June 5, 1906:

TABLE 12.—*Patents granted to June 5, 1906.*

CLASS.	Total.	Jan. 1, 1902, to June 5, 1906.	Prior to 1902.
Total	46,729	4,828	41,901
Plows:			
Including cotton choppers and scrapers, cultivators, etc., parts and attachments	12,799	1,175	11,624
Harrows and diggers:			
Including clod crushers, forks, hoes, land rollers, potato diggers, rakes, shovels, stalk choppers, transplanters, etc., parts and attachments	6,430	944	5,486
Seeders and planters:			
Including broadcast, checkrow, drills, fertilizer distributers, etc., parts and attachments	9,411	862	8,549
Harvesters:			
Including binders, fruit gatherers, hand binders, hay loaders, horse rakes, mowers, scythes, and cradles, etc., parts and attachments	12,431	1,136	11,295
Separators and thrashers:			
Including band cutters and feeders, cane strippers, clover hullers, corn husking machines and implements, cornshellers, fruit and vegetable separators, etc., parts and attachments	5,658	711	4,947

Exports.—The exportation of agricultural implements is one of the most important branches of the American export trade in manufactured articles, ranking fourteenth among all classes. Compared with the value of the other classes of exported machinery agricultural implements are far in the lead, being nearly twice as great as that of carriages, cars, other vehicles, etc.; and builders' hardware and saws and tools. The United States leads the world in the exportation of agricultural implements, with the United Kingdom as its principal competitor.

Table 13 shows the value of agricultural implements exported each year from 1900 to 1905; distributed by class and country.

TABLE 13.—VALUE OF EXPORTS OF AGRICULTURAL IMPLEMENTS: YEARS ENDING JUNE 30, 1900 TO 1905.[1]

CLASS AND COUNTRY.	1905	1904	1903	1902	1901	1900
Aggregate	$20,721,741	$22,749,635	$21,006,622	$16,286,740	$16,313,434	$16,099,149

[1] Bureau of Statistics, Department of Commerce and Labor, "Commerce and Navigation of the United States."

In the fifteen years 1890 to 1905 the extension of trade to foreign countries has been very great. The value of exports during the fiscal year 1905 formed 18.5 per cent of the total value of products for the census of 1905; for 1900 the ratio was 15.9 per cent. The absolute increase in value from 1900 to 1905 was more than $4,000,000 and from 1890 to 1905 between $16,000,000 and $17,000,000.

The value of agricultural implements exported during the fiscal years 1870, 1880, and 1890, together with their percentages of the total value of products of the industry for the census years 1870, 1880, and 1890, are as follows: 1870, $1,068,476, or 2.1 per cent; 1880, $2,245,742, or 3.3 per cent; and 1890, $3,859,184, or 4.7 per cent.

Almost every agricultural country in the world imports American implements in quantities governed by its industrial and economic condition. The use of labor-saving machinery for agricultural purposes naturally depends largely on the cost of labor. This was revealed by the 54 replies received from United States consuls to a Department circular sent at the request of the National Association of Agricultural Implement and Vehicle Manufacturers, which indicated that where the cost of farm labor is low very few agricultural implements are used. The higher the wage the greater the demand for the up to date implements.

Russia and Argentina, the two great wheat producing countries, were in 1905 the leading importers of American agricultural machinery. Russia received 18.6 per cent of the total value of all exports, nearly four times as much as in 1900, and Argentina 24.3 per cent, an actual increase since 1900 of 178.7 per cent.

Of all the economy effected by labor-saving machines, the saving resulting from the use of machines in harvesting the corn and wheat crops is greater than any other, and that obtained in the harvesting of the wheat crop probably greatest. Moreover, evidence confirming the statement already made that the demand is intensified in countries where labor is expensive or hard to obtain is found in the report of the American consul at Odessa in 1903 where he writes that at that time labor was so scarce in many places that troops were sent to work in the fields. In Argentina the scarcity and consequent high price of labor renders the use of labor-saving machinery a necessity. Much of the land suitable for wheat growing in that country is not as yet under cultivation, and in the opening up of this land lies an opportunity for agricultural implements similar to, though less extensive than, that which came from the opening up of the West.

DIAGRAM 2.—*Growth of the total value of exports and of total value of exports to specified countries: 1890 to 1905.*

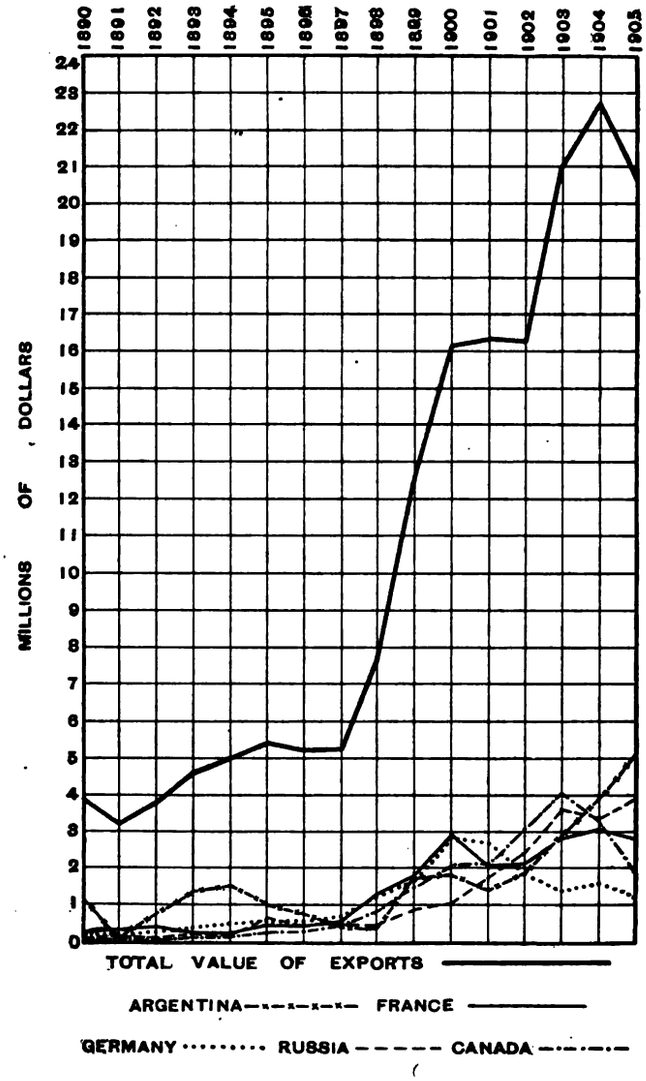

Table 14, which follows, is a full statement by states of the agricultural implement industry as reported at the census of 1905.

TABLE 14.—AGRICULTURAL IMPLEMENTS—

		United States.	California.	Connecticut.	Georgia.	Illinois.
1	Number of establishments	648	25	3	16	82
2	Capital, total	$196,740,700	$2,240,143	$320,374	$792,004	$71,383,289

TABLE 14.—AGRICULTURAL IMPLEMENTS—

		United States.	California.	Connecticut.	Georgia.	Illinois.
	Kind and quantity of products, number of implements—Continued.					
	Implements of cultivation—Continued.					
81	Celery hillers	1,070				20
82	Cotton scrapers	22,519			3,981	3,900
83	Cotton sweeps	8,098			2,026	867
84	Equalizers	67,852				52,550
	Harrows—					
85	Disk	104,323	171	4,000		44,418
86	Spring-tooth	86,408				1,200
87	Spike-tooth	262,442	386		4,789	112,180
88	Hoes, dozens	331,620		39,155		51
89	Markers and furrowers	5,512				4,033
	Plows—					
90	Disk	39,146	990	400		19,478
91	Shovel	121,899	30		4,674	5,977
92	Steam	1,599	20			23
93	Sulky or wheel	138,899	58	300		85,403
94	Walking	956,898	1,264		125,779	157,906
95	Potato coverers and hillers	2,938				
96	Rollers	22,188	12	15		231
97	Stalk cutters	15,146				8,822
98	All other	12,480	367			9,293
	Harvesting implements—					
99	Grain cradles	30,056				
100	Harvesters and binders and headers, grain	108,810	227			78,018
	Harvesters—					
101	Bean	665	35			
102	Corn	6,924				1,628
103	Other	3,161	2			36
104	Hay carriers	85,121	6			27,751
	Hayforks—					
105	Hand, dozens	345,297				
106	Horse	62,801	2,190			
107	Hay loaders	27,174	1			18,158
	Hayrakes—					
108	Hand, dozens	76,139				
109	Horse	236,297	371			120,926
110	Hay stackers	8,670	89			560
111	Hay tedders	35,745				1,019
112	Mowers	267,692				170,826
113	Mowers and reapers combined	5,693				16
114	Potato diggers	11,703				1,592
115	Potato hooks	139,940				
116	Reapers	60,996				35,856
117	Scythes	705,025		79,026		
118	Scythe snaths	699,636				
119	Sickles	247,716				
120	Stackers	845				
121	All other	6,659	1,449			237
	Seed separators—					
122	Bean separators	727	1			
123	Other separators	12,109				412
124	Clover hullers	351				
125	Corn huskers	1,327				583
	Cornshellers—					
126	Hand	47,189				10,653
127	Power	6,082				2,573
128	Fanning mills	22,994	1			300
	Thrashers—					
129	Horsepower	2,237	5			
130	Steampower	7,950	3			513
131	All other	1,182			47	950
	Miscellaneous—					
132	Bean pullers	1,587				221
133	Cane mills	2,996	30		1,071	
134	Carts	21,365	480			10,890
135	Check rowers	12,478				10,363
136	Corn cleaners	106				106
137	Corn hooks	44,628				
138	Corn knives	125,149		990		
139	Cotton gins	72			50	
140	Cotton presses	18				
141	Ensilage cutters	10,696				174
142	Engines and boilers	389				
143	Farm trucks	4,320	172			1,125
144	Gardening implements	494,034			1,350	15,767
145	Grubbing machines	1,043				165
146	Hand carts	9,359				2,739
147	Hay-cutters	29,283				
148	Hay presses	5,719	8		30	1,963
149	Hayracks	620				
150	Horsepowers	4,804	73			2,615
151	Lawn mowers	34,000				27,000
152	Pea hullers	1,706			412	
153	Portable sawmills	1,828	50			
154	Portable steam engines	1,190				
	Pumps—					
155	Hand	81,765				13,932
156	Horse	1,000				1,000
157	Steam	165				135
158	Road carts	373	12			
159	Shovels, spades, and scoops	868,899				
160	Singletrees	220,549	1,350		124,896	
161	Sirup evaporators	768			768	
162	Sorghum evaporators	2,447			874	
163	Straw stackers	8,034				715
164	Thrasher trucks	1,269				
165	Traction engines	6,165	29			397
166	Wagons	7,027	133			1,161
167	Wagon trucks	54	4			
168	Water trucks	2,077				18
169	Weeders	12,224	1,050	150		
170	Windmills	2,009				1,934

TABLE 14.—AGRICULTURAL IMPLEMENTS—

		Missouri.	Nebraska.	New Hampshire.	New Jersey.	New York.	North Carolina.
1	Number of establishments	21	3	8	10	75	13
2	Capital, total	$1,299,575	$134,600	$62,100	$432,195	$23,436,429	$116,735
3	Land	$138,550		$3,250	$21,375	$1,001,905	$3,960
4	Buildings	$191,914	$15,000	$9,000	$75,967	$2,926,797	$23,600
5	Machinery, tools, and implements	$185,020	$60,300	$16,400	$54,767	$2,998,146	$27,550
6	Cash and sundries	$784,091	$59,300	$33,450	$280,086	$16,509,581	$61,625
7	Proprietors and firm members	18	2	11	9	66	13
	Salaried officials, clerks, etc.:						
8	Total number	89	11	3	37	934	8
9	Total salaries	$93,161	$6,000	$2,200	$40,005	$909,322	$9,250
	Officers of corporations—						
10	Number	13	2		8	53	6
11	Salaries	$29,100	$2,500		$13,050	$144,912	$7,600
	General superintendents, managers, clerks, etc.—						
12	Total number	76	9	3	29	881	2
13	Total salaries	$64,061	$3,500	$2,200	$26,955	$664,410	$1,650
	Men—						
14	Number	70	9	2	27	809	2
15	Salaries	$60,637	$3,500	$1,900	$26,445	$632,480	$1,650
	Women—						
16	Number	6		1	2	72	
17	Salaries	$3,424		$300	$510	$31,930	
	Wage-earners, including pieceworkers, and total wages:						
18	Greatest number employed at any one time during the year	845	69	71	326	8,516	160
19	Least number employed at any one time during the year	360	5	33	95	2,897	103
20	Average number	525	25	45	204	6,279	107
21	Total wages	$261,116	$15,025	$24,767	$89,787	$3,240,885	$30,883
	Men 16 years and over—						
22	Average number	521	25	45	204	6,251	103
23	Wages	$260,181	$15,025	$24,767	$89,787	$3,233,585	$30,328
	Women 16 years and over—						
24	Average number	1				19	
25	Wages	$300				$4,789	
	Children under 16 years—						
26	Average number	3				9	4
27	Wages	$635				$2,511	$555
	Average number of wage-earners, including pieceworkers, employed during each month:						
	Men 16 years and over—						
28	January	537	7	53	245	7,392	121
29	February	560	7	46	271	7,707	125
30	March	571	17	59	286	7,741	120
31	April	616	33	64	298	7,358	113
32	May	633	34	64	259	6,520	94
33	June	598	38	37	239	6,124	85
34	July	534	60	29	108	5,111	82

37	October	399	19	45	143	4,927	108
38	November	435	19	48	160	6,103	110
39	December	449	5	43	201	6,834	112
40	Miscellaneous expenses, total	$57,362	$6,574	$4,449	$53,082	$1,329,244	$5,108
41	Rent of works	$4,029	$435	$100	$400	$6,382	$140
42	Taxes	$3,564	$108	$422	$1,159	$62,600	$788
43	Rent of offices, interest, insurance, and all other sundry expenses not hitherto included.	$48,487	$6,031	$3,927	$50,323	$1,259,841	$3,755
44	Contract work	$1,282			$1,200	$421	$425
45	Materials used, aggregate cost	$452,056	$13,686	$13,568	$117,596	$5,678,339	$50,950
46	Principal materials, total cost	$361,299	$12,521	$10,425	$108,417	$4,127,262	$40,554
47	Purchased in raw state			$2,260		$5,109	
48	Purchased in partially manufactured form	$361,299	$12,521	$8,165	$108,417	$4,122,153	$40,554
49	Fuel	$15,190	$227	$2,120	$4,524	$227,673	$3,185
50	Rent of power and heat		$80			$5,770	
51	Mill supplies	$4,341	$38	$403	$970	$42,909	$420
52	All other materials	$58,041	$170	$620	$1,265	$1,214,238	$4,391
53	Freight	$13,185	$650		$2,420	$60,487	$2,400
54	Products, total value	$1,068,008	$46,000	$61,860	$391,926	$13,045,891	$126,865
55	Seeders and planters	$40,115	$36,000		$74,912	$1,800,182	$24,000
56	Implements of cultivation	$226,333	$7,500	$3,950	$187,243	$2,545,947	$46,070
57	Harvesting implements	$291,189		$47,600	$2,000	$5,841,389	$1,100
58	Seed separators	$45,389			$14,133	$461,814	
59	Miscellaneous	$362,821	$2,500		$85,401	$1,410,520	$8,495
60	All other products	$85,882		$9,500	$19,047	$889,596	$33,225
61	Amount received for repair work, etc	$16,279		$810	$9,190	$96,443	$13,975
	Kind and quantity of products, number of implements:						
	Seeders and planters—						
	Planters—						
62	Bean				45		
	Corn—						
63	Hand	750				2,445	
64	Horse					950	50
65	Cotton						4,750
66	Potato				934	250	
	Drills—						
67	Beet						
68	Corn	357				1,268	
69	Grain	125	1,000			11,948	
70	Grain sowers					118	
71	Lime spreaders					34	
72	Listers	1,060					
73	Manure spreaders				906	8,594	300
74	Seed sowers	700			2,601	1,375	
75	Tobacco transplanters					100	
76	All other						
	Implements of cultivation—						
	Cultivators—						
77	Bean						
78	Beet						
79	Small	1,804			11,759	23,746	6,000
80	Wheeled	7,607			3,275	3,721	455

[1] Includes establishments distributed as follows: Alabama, 2; Arkansas, 1; Colorado, 1; Maryland, 2; North Dakota, 1; Oregon, 1; South Dakota, 2; Utah, 1; Washington, 1; West Virginia, 1.

ELECTRICAL MACHINERY, APPARATUS, AND SUPPLIES

ELECTRICAL MACHINERY, APPARATUS, AND SUPPLIES.

By THOMAS COMMERFORD MARTIN, Expert Special Agent.

The first complete record made by any government of the manufacture of electrical apparatus and supplies was that included in the Twelfth Census of the United States. Prior to this, general and miscellaneous figures had been secured, which, however, had reference rather to specific industries and developments than to the electrical arts as a whole.

At the censuses of 1880 and 1890 general statistics were obtained as to the number of electrical manufacturing establishments, their gross products, capital invested, number of wage-earners, wages paid, cost of materials, and a few other items. But Census Bulletin No. 245, of August 25, 1902, was the first to summarize or to analyze the entire product of American electrical factories and to discuss the conditions of electrical manufacturing as a great and growing field of American inventiveness, industry, and investment. That bulletin was followed in due sequence by a series of reports on the generation and utilization of electric current employing the machinery and apparatus furnished by the electrical manufacturing industries. One of these reports dealt exhaustively with street and electric railways; another with central electric light and power stations; and a third with telephones and telegraphs, including municipal fire alarm and police patrol systems. In fact, with the issuance of the Report on Telephones and Telegraphs, January 23, 1906, the Bureau of the Census closed the first and only census ever taken of the group of arts and industries dealing with the employment of the electric current for transportation, illumination, distribution of power, the long distance transmission of speech, and the instantaneous communication of messages and intelligence. The present bulletin, dealing with figures of electrical manufacturing for the census of 1905, begins in reality the new series of reports on these allied industries, as hereafter the census of street railways, lighting plants, and telephone and telegraph systems will be taken in five-year instead of ten-year periods. The rapidity of growth in these fields is probably unsurpassed in any other branch of human activity, and the more frequent record of these statistics adds greatly, therefore, to their value and utility.

In the report on electrical industries for 1900 a large quantity of products for which an electrical use could be predicated was excluded; these figures are, however, included within the scope of other Census inquiries. Among the products excluded then and now, were poles, whether of wood, iron, or steel; a large amount of glass and porcelain ware made only for electrical purposes; bare iron and copper wire; and the whole group of electro-chemical and electro-metallurgical products.

The extent of items of this character excluded may be gathered from the fact that the electrical conduits reported by the pottery, terra cotta, and fire clay industry for 1905 reached a value of $602,682 in the class of terra cotta, fire and other clay products. The products reported as of the nature of porcelain electrical supplies reached a value of $1,500,283, as compared with a total of only $470,355 at the census of 1900. The product of electrical conduits in 1900 was reported as valued at $685,273, so that while the conduit showed a slight decrease in the period, the porcelain electrical supplies showed apparently an enormous increase. It would not be safe, however, to take these figures on their face, and the great gain in porcelain may be attributed to the inclusion of goods or supplies which might more strictly have been included within the statistics of electrical industries in 1900. Some of the largest electrical manufacturers have purchased or equipped separate porcelain factories, and one of them has an extensive porcelain department carried on in close connection with its other shops of an entirely

different nature. As will be seen, however, these two items for 1905 make a total of $2,102,965, not included in the electrical returns, but obviously bearing a very intimate relationship to that generic class of apparatus and supplies. It is to be observed that in Table 17, relating to electrical conduits, almost the entire product reported deals with interior conduits, which are of a metallic or textile nature in general; only short sections, such as those for running through floors or penetrating exterior walls, being of porcelain. Apparently the porcelain sections are not here included, as they are not regarded as conduits in the electrical trade, but are usually spoken of as "tubes." Undoubtedly a large quantity of this material is therefore embraced in the porcelain item just referred to, while in like manner none of the terra cotta and other clay conduits has been brought to account in the small amount of underground conduits enumerated in Table 17.

Table 1 presents the comparative figures of electrical machinery, apparatus, and supplies for 1880, 1890, 1900, and 1905.

TABLE 1.—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1880 TO 1905.

	CENSUS.				PER CENT OF INCREASE.		
	1905	1900 [1]	1890	1880	1900 to 1905	1890 to 1900	1880 to 1890
Number of establishments	784	581	189	[2] 76	34.9	207.4	148.7
Capital	$174,066,026	$83,659,924	$18,997,337	$1,509,758	108.1	340.4	1,158.3
Salaried officials, clerks, etc., number	13,619	5,067	[3] 683	(4)	109.6	641.9	.....

Wage-earners, average number	60,466	42,013	8,802	1,271	43.9	377.3	592.5
Total wages	$31,841,521	$20,579,194	$4,517,050	$683,164	54.7	355.6	561.2
Men 16 years and over	48,976	34,462	7,289	1,132	42.1	372.8	543.9
Wages	$28,316,772	$18,513,653	$4,082,847	(4)	53.0	353.4	.....
Women 16 years and over	10,902	6,956	1,469	72	56.7	373.5	1,940.3
Wages	$3,410,081	$1,943,220	$426,660	(4)	75.5	355.4	.....
Children under 16 years	588	595	44	67	[5] 1.2	1,252.3	[5] 34.3
Wages	$114,668	$122,321	$7,543	(4)	[5] 6.3	1,521.6	.....
Miscellaneous expenses	$17,948,708	$6,804,633	$1,154,462	(6)	163.8	489.4	.....
Cost of materials used	$66,836,926	$49,458,272	$8,819,498	$1,116,470	35.1	460.8	689.9
Value of products, including amount received for custom work and repairing	[7] $140,809,369	[8] $92,434,435	$19,114,714	$2,655,036	52.3	383.6	619.9

[1] The totals for 1900 do not agree with those published at the Twelfth Census because of a reclassification.
[2] Includes 36 establishments reported as "electrical apparatus and supplies," and 40 reported as "telegraph and telephone apparatus."
[3] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Decrease.
[6] Not reported.
[7] Exclusive of electrical machinery, apparatus, and supplies, valued at $18,742,033, made by establishments engaged primarily in the manufacture of other products.
[8] Exclusive of electrical machinery, apparatus, and supplies, valued at $13,397,430, made by establishments engaged primarily in the manufacture of other products.

In spite of the general tendency toward the consolidation of manufacturing establishments there was a gain in number of 34.9 per cent between 1900 and 1905, while the capital increased 108.1 per cent. Other large increases will be noted in the number of salaried officials and wage-earners, and particularly in the amounts paid out to employees. Throughout the last five years labor has been actively and remuneratively employed in all the electrical industries and no single strike of any serious magnitude has been recorded.

The increase in the total value of products, 1900 to 1905, was 52.3 per cent, which is a good indication of the capacity of the field at large for consumption, although various factors have come in to establish wide differences in the increase in the respective departments of the electrical business. In many instances, moreover, while the general trend of prices has been upward the cost of electrical apparatus to the consumer has been less, owing to large production and greater refinements in the processes. This has been affected, however, by the higher cost of such raw material as copper, the price of which has risen steadily throughout the entire term.

The growth of the industry since 1880, as shown by the census figures, is a remarkable illustration of the ingenuity of inventors, and the enterprise of manufacturers, in creating and supplying, during the past twenty-five years, an ever-enlarging demand for electrical machinery, apparatus, and supplies. The increase in number of establishments has been over ninefold, and in average number of wage-earners more than forty-six fold. The wages paid, amounting in 1880 to a little less than $700,000, reached, at the census of 1905, a total of nearly thirty-two millions, the gain being greater than forty-five fold. In value of products the increase has been over fifty-two fold.

Table 2 compares the general statistics, by states, for 1900 and 1905.

TABLE 2.—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

[1] Exclusive of electrical machinery, apparatus, and supplies, valued at $18,742,033, made by establishments engaged primarily in the manufacture of other products. This value was distributed as follows: California, $81,600; Connecticut, $591,094; Illinois, $1,056,263; Indiana, $252,208; Maryland, $400; Massachusetts, $14,900; Michigan, $217,131; Missouri, $205,745; New Hampshire, $28,185; New Jersey, $5,130,814; New York, $5,494,909; Ohio, $1,557,660; Pennsylvania, $2,683,549; Rhode Island, $339,666; Wisconsin, $599,000; and "all other states," $488,909.

[2] The totals for 1900 do not agree with those published at the Twelfth Census because of a reclassification.

[3] Exclusive of electrical machinery, apparatus, and supplies, valued at $13,397,430, made by establishments engaged primarily in the manufacture of other products.

[4] Includes establishments distributed as follows: Delaware, 1; District of Columbia, 2; Georgia, 2; Iowa, 2; Louisiana, 2; Maine, 2; Nebraska, 2; Oregon, 2; South Carolina, 1; Tennessee, 2; Texas, 3; Virginia, 2; Washington, 1; West Virginia, 1.

[5] Includes establishments distributed as follows: Delaware, 1; Georgia, 1; Iowa, 2; Louisiana, 2; Maine, 2; Nebraska, 3; North Carolina, 2; South Carolina, 1; Tennessee, 1; Texas, 1.

The distribution of electrical manufacturing throughout the states has remained the same in all essential respects at the two censuses. New York, Illinois, Ohio, Pennsylvania, and Massachusetts reported at the census of 1905, 523 out of 784 establishments making electrical apparatus, or two-thirds (66.7 per cent). If to these be added the 32 establishments in Connecticut, the 34 in Indiana, and the 42 in New Jersey, it will be seen that 631 out of 784 establishments are concentrated in these eight states. Incandescent lamps are made all over the country, but the largest output is from a plant in New Jersey, which also makes many of the best electrical instruments (although in this respect Massachusetts is also well to the front). The manufacture of insulated wires and cables has had its center on the Atlantic seaboard, particularly in the states of Massachusetts, Connecticut, Rhode Island, New York, and New Jersey, but such material was also produced in large quantities farther west. While the production of telephonic apparatus has always been large in Illinois, this industry has undergone development in several other of the Western

states, due to the "independent" telephone movement; and in the Middle states one or two of the largest plants being in New York. A few of the plants enumerated were brought into being by their proximity to lumber regions, affording a supply of insulating pins, cross-arms, etc.

The gross values of the output at the census of 1905, as shown by Table 2, were in close proportion to the number of establishments, but the states do not come in quite the same order. New York led, followed by Pennsylvania, Illinois, Massachusetts, New Jersey, and Ohio, in the order given. If the amounts for these states be totaled, it will be seen that the great bulk of all products, or over five-sixths of the whole (84.5 per cent) came from these 6 states.

The great increase in the amount of capital invested in the period has been referred to. In 1900 the $83,659,924 of capital invested had, so to speak, reproduced itself during the year with a margin of almost $9,000,000, the value of the products being $92,434,435. In the year 1905, however, the capitalization of $174,066,026 returned was associated with a production valued at $140,809,369—an indication of an undue increase in the capitalization. According to Table 2 this increase was distributed uniformly throughout the country, but was greatest by far in the state of Pennsylvania, where the increase was from $20,967,587 to no less a sum than $58,393,011; in other words, there was an increase of capital in that state of 178.5 per cent, although the value of products increased only from $19,112,665 to $26,257,569. In New York state the capitalization increased from $17,697,352 to $30,643,167, but the value of the products rose from $22,695,024 to $35,348,276. Another notably large increase in capitalization was that in Illinois, where it rose from $11,641,177 to $21,644,783, while the products increased only from $12,169,425 to $16,700,027. In New Jersey the capitalization increased 133.4 per cent, namely, from $7,909,120 to $18,457,821, but the value of the products exhibited a similarly large increase, namely, from $7,532,700 to $13,803,476. Ohio exhibited a more normal ratio of increase in capital and product, as the capital increased from $7,036,103 to $10,408,184, while the products rose from $6,504,847 to $11,019,235. In Massachusetts also the ratio ran about the same, the capitalization increasing from $8,259,612 to $12,735,427, while the value of the products rose from $10,490,361 to $15,882,216. These are the larger figures, while at the other end of the scale, as shown by Table 2, were several states in which the electrical product as well as the invested capital was insignificant. Fourteen states in 1905, with a total of 25 manufacturing establishments, reported a capital of only $625,492 and products valued at $777,780. There was, however, a noteworthy increase in Minnesota, where the capitalization increased 386.9 per cent in the period, namely, from $79,935 to $389,211, with a product valued at $423,933.

PRODUCTS IN DETAIL.

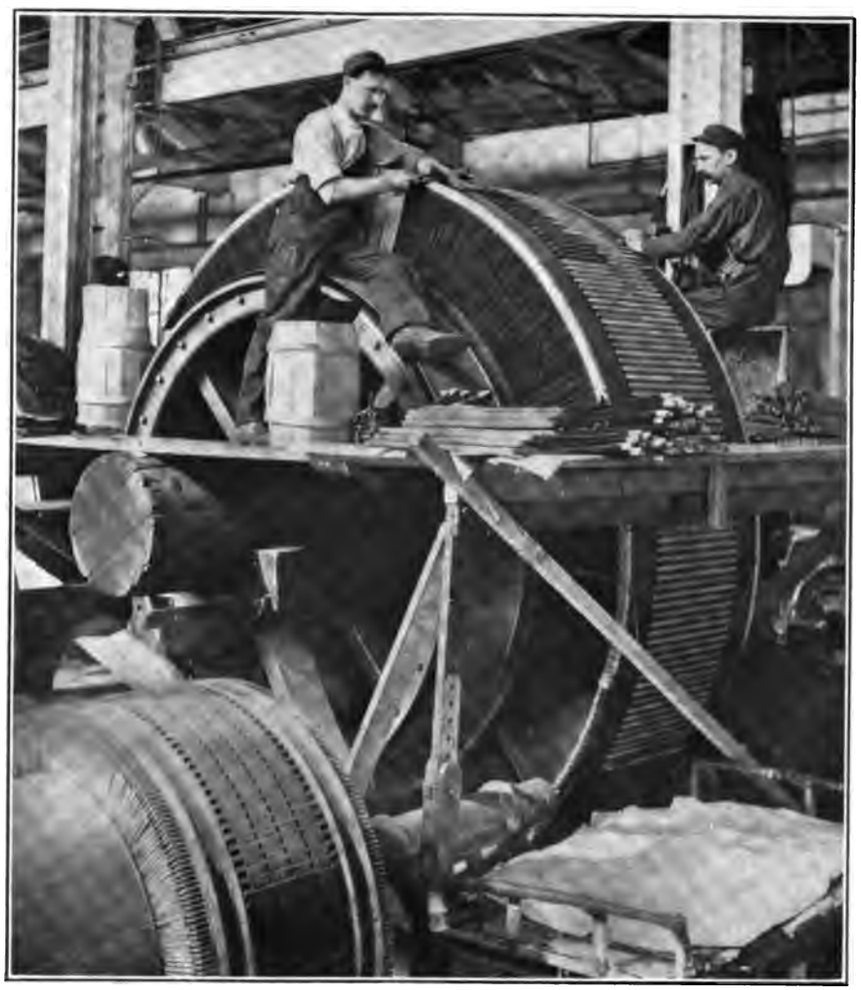
Practically little of the vast production of electrical machinery, apparatus, and supplies goes across the counter directly into the hands of individual consumers. The great bulk of it is purchased and consumed by public service corporations. There are relatively few electrical stores or jobbing houses for retail trade, and even these find their patronage mostly among the electrical contractors. There are no large department stores or other agencies of retail trade through which this vast aggregate of electrical apparatus and supplies can be distributed, but, on the other hand, there were in 1902, 987 operating and lessor street railway companies which constituted the only market for street railway apparatus, and 3,620 private or municipal central station lighting plants, which with some 50,000 isolated plants constituted almost the entire market for electric lamps of all kinds. The third large field of public service electrical consumption was afforded by 25 large telegraph systems and 4,151 telephone systems, in which was used an overwhelming proportion of the telegraphic and telephonic apparatus. Supplementing these intelligence systems there were also in 1902, 764 municipal electric fire alarm systems and 148 electric police patrol systems. It will be readily understood, therefore, that after these large channels of consumption had been filled very little of the apparatus or material was left for the retail purchaser whose average wants, indeed, are limited to an occasional incandescent lamp, a fan motor, a push button, or a few feet of wire. All of these departments, except perhaps that of telegraphy, have made gigantic strides in the last five years, and to their prosperity, therefore, must be attributed the general well-being of electrical manufacturing as exhibited in Tables 1 and 2.

In addition to the electrical products manufactured by the 784 establishments in 1905 and the 581 in 1900, shown in Tables 1 and 2, a large quantity of electrical machinery and apparatus was made by establishments engaged primarily in the manufacture of other products. The value of such products as reported at the censuses of 1900 and 1905 was $13,397,430 and $18,742,033, respectively. The distribution by states of the total for 1905 is shown in a footnote to Tables 2 and 27. The magnitude of this electrical manufacturing carried on in establishments in which it is not the chief product or sole business, is illustrated by the fact that the total of $18,742,033 at the census of 1905 was produced by no fewer than 128 establishments located in 25 states, giving an average value per establishment of $146,422.

The above partial products for both 1905 and 1900, while not included in Tables 1, 2, and 27 of this report, are included in their respective groups in the detailed tables, which present the products by kind, quantity, and value.

Tables 3 to 26, inclusive, give in detail the statistics

CONSTRUCTING A LARGE ALTERNATING CURRENT TRANSFORMER.



BUILDING UP THE ARMATURE OF A LARGE ELECTRIC GENERATOR.

for the different varieties of electrical apparatus and supplies manufactured. Comparative figures for the total for the United States are presented for the comparable products that were reported separately at the censuses of 1900 and 1905. In a number of the states there were only one or two establishments engaged in the manufacture of some of these different classes of products, and to present the statistics for them would result in disclosing the operations of individual establishments. Therefore the totals for 1905 are given by states only in cases where such a presentation does not result in giving figures for less than three establishments engaged in the manufacture of any distinct class of products.

Dynamos.—The statistics with regard to the production of dynamos are presented in Table 3.

TABLE 3.—DYNAMOS—NUMBER, HORSEPOWER, AND VALUE: 1905 AND 1900.

[1] Included in "all other states."
[2] Includes states as follows: California, Connecticut, Kentucky, Maine, Minnesota, New Hampshire, Texas, Virginia, and Washington.
[3] Includes states as follows: Illinois, Indiana, Massachusetts, Minnesota, Missouri, New Hampshire, New Jersey, New York, Pennsylvania, and Wisconsin.

Before proceeding to a detailed discussion of dynamos as a class, it may be well, in view of the importance of the generic group of dynamo electrical machinery, to point out that the total value of dynamos and motors produced was $33,454,860. This does not include dynamotors, etc., which may be classed with transformers. Dynamos and motors constitute the largest single class of apparatus dealt with, and go into service in every department of electrical industry, either as the source of electrical energy or as the means of power distribution. These machines are employed chiefly in the three great departments, traction, lighting, and power, which are to-day frequently supplied from one power house, the electrical energy generated being manipulated by subsidiary devices to render it available for its specific use at the point of consumption. It is true that the value returned for insulated wire and cable was $34,519,699, but this material was supplied to all the electrical arts in varying proportions and no small part was required for use with the dynamos and motors, the installation of which demands these arteries of connection. In like manner the carbons, valued at $2,710,935, the arc lamps, valued at $1,574,422, and the incandescent lamps, valued at $6,953,205, were to a very large degree necessary supplies for the lighting arts that could not be carried on without the modern dynamo. Incidentally, also, it may be noted that no less an amount than $77,539,359 remained for other electrical products, exclusive of "amount received for custom work and repairing." This large amount embraced much apparatus dependent upon or associated with dynamo electrical machinery.

It will be seen from Table 3 that the value of dynamos reported in 1905 was very little in excess of that reported at the previous census, being $11,084,234 as compared with $10,472,576. As the other figures with regard to this class of apparatus indicate, the slight increase in value was associated with a very large increase in number and in horsepower; the number of machines built increasing from 10,527 in 1900 to 15,080 in 1905, while the capacity nearly doubled, rising from 770,832 horsepower to 1,328,243 horsepower. It is obvious from even a cursory consideration of these figures that a relatively small increase in the average size of the machines was accompanied by an enormous decrease in the cost per horsepower to the purchaser. The average size of machines reported in the earlier census was 73 horsepower, and this had risen in 1905 to 88 horsepower. Meantime, however, the cost had decreased from $13.59 per horsepower to $8.35. This change is due entirely to the great increase in the number of large machines in the power plants of central stations and electric railways. In earlier years the work of these plants was done chiefly with machines of very moderate capacity—50 horsepower being a respectable size for an arc lighting dynamo and 500 horsepower for incandescent lighting or electric railway work. The growing demand for current for all classes of service, and the greater distances and larger areas for which this current must be supplied, led to the adoption of alternating current dynamos generally associated with transforming apparatus to which the electrical energy could be delivered at the point of consumption, in order that, if necessary, direct current could be furnished to

trolley cars, storage batteries, arc lamps, etc. The whole process of the change is exemplified in the fact that, whereas the direct current machines averaged 47 horsepower in 1900, the 13,756 reported in 1905 had risen to an average of but 62 horsepower per machine, and the average size of the alternating current dynamos had risen from 254 to 358 horsepower. Moreover, while the direct current machines were ten times as numerous, they had not quite twice the total capacity of the 1,324 alternating current machines.

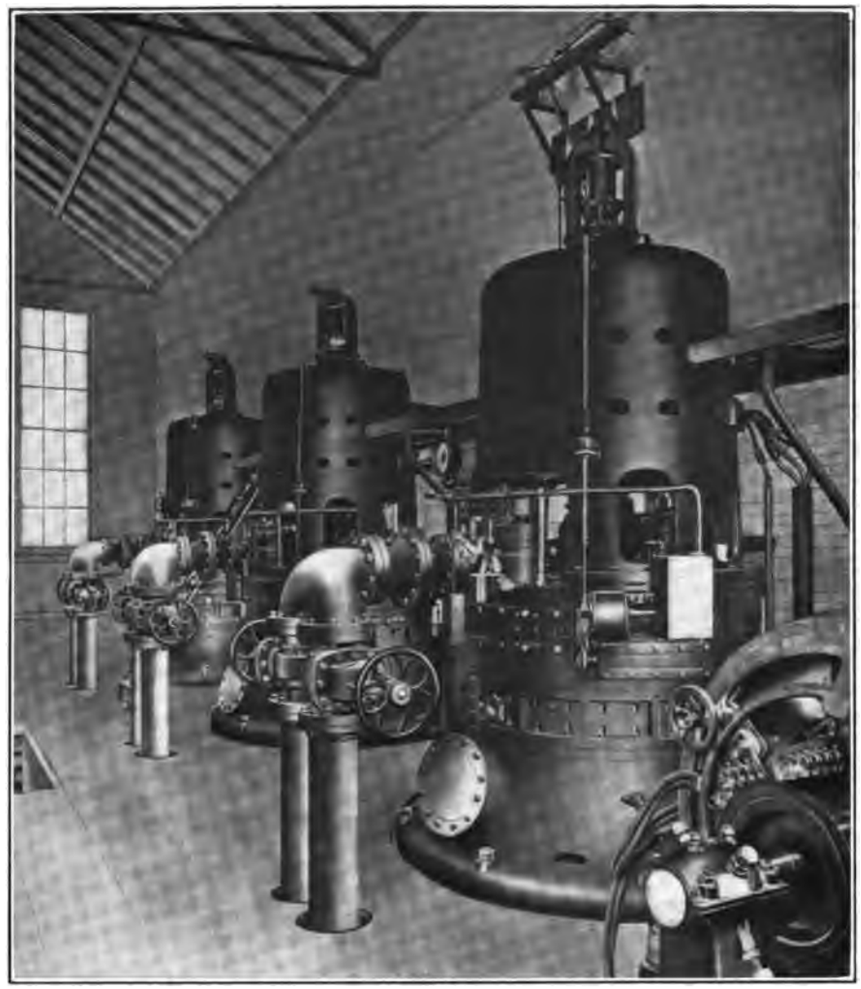
As these figures indicate, while the dynamo art as a whole has already undergone a great revolution with regard to its apparatus for producing current in bulk for great public utilities, and resorts increasingly to the use of alternating current, there is still an insistent demand for large numbers of small dynamos of the direct current type. Ten or fifteen years ago machines of from 50 to 100 horsepower were popular for arc lighting, but now the current for arc lamps is supplied quite generally from the gigantic machines which at the same time furnish current for incandescent lighting and for power. On the other hand, the adoption of electric lighting for steamships, large office buildings, isolated country estates, and scattered mills, factories, etc., has maintained a steady demand for direct current dynamos for incandescent lighting, many of them being employed also in the daytime to furnish electrical energy for motive power purposes. There is a marked tendency in the great cities to abandon the isolated plants in large buildings and to connect with the service mains of the central station companies, but at the same time many of these plants have capacity enough to supply an ordinary town, and being economically self-sufficient are likely to remain in operation indefinitely. A few plants in recent years have been installed on farms to be operated by wind or water power, but the number of these plants during the census year was too insignificant to warrant special inquiry. In many instances central stations have annexed large sections of rural territory to their circuits, thus supplying not only a city or large town, but a great number of farmers, dairymen, etc. Frequently the country districts secure current from the circuits of the interurban trolleys which now constitute so large a network in many of the more thickly settled regions of the country.

Probably a large proportion of the capacity of direct current dynamos is manufactured and employed especially for electro-chemical processes. Electroplating work is done with this type of current at such low voltages that the ordinary city current can not be employed for the purpose unless it is used to drive a motor which in turn operates the low voltage plating machines. It is, however, in electro-deposition and electro-chemical operations that such apparatus in its largest units finds the greatest demand. This is particularly true of the refining of copper. The first electrolytic copper refining process employed for industrial purposes was that of James Elkington, in Wales, in 1869, with an output of about 250 pounds of copper. A few years later the work was taken up in Germany, while in the United States only one plant is recorded as having been in operation as late as 1878. Until 1890 the development of this work was relatively slow, but since that time it has undergone enormous development, so that in 1905 nine large plants for the electro-deposition of copper were recorded as in operation in the United States, all of them employing large capacity, low voltage, direct current dynamos. The largest of these American plants has a capacity of refining 350 tons of copper per day. Not only is the economy of the process such as to explain this extension of electrical methods, but the value of the by-product is enormous, it being stated that at the Anaconda refinery alone over $200,000 monthly is recovered in gold and silver from the slimes of the copper vats.

The alternating current dynamos included in Table 3 are of three types, their nature depending somewhat on the uses to which they have to be applied, namely, single phase, 2-phase, and 3-phase. In outward appearance and general characteristics these machines present a uniform appearance, but their style of construction depends upon whether they are to be operated by steam engines, gas engines, or driven by water turbines, and is modified again by the use of steam turbines instead of reciprocating engines.

In the earliest days of electric lighting, single phase alternating current dynamos were employed, but being utilized in a desultory way fell into unpopularity, which lasted until the great revival of alternating current methods about 1885. Then the increased use of incandescent lighting rendered it desirable to cover circuits of much larger area than was possible with the direct current apparatus of low voltage, as this current could not be delivered economically much more than a mile from the central station. The alternating current dynamo, generating current at high pressure and delivering its product to transformers miles apart, where it could be lowered in pressure for the consumption circuits of the customer, leaped swiftly into prominence and importance at this juncture. This created such a revolution in the art that to-day, for example, not one of the great Edison systems, in such cities as New York, Boston, Chicago, Philadelphia, etc., hesitates to restrict the employment of direct current dynamos to generate current at a pressure of 250 volts, or less, and generates alternating current in huge power houses only, transmitting this at pressures of 6,000 or 7,000 volts to substations where it is converted into low pressure direct current for distribution and use.

The earlier single phase apparatus was practically available for lighting purposes only and was usually employed with a large number of reversals of current per minute, the frequencies running from 60 cycles per second upward. Such current could not be used for



THREE 500 KILOWATT TURBINE DIRECT CONNECTED GENERATORS INSTALLED IN A RAILROAD REPAIR SHOP.

FACTORY EQUIPPED WITH STEAM TURBINE DYNAMO ELECTRIC UNITS FOR SUPPLYING LIGHT AND POWER.

electroplating or for charging storage batteries, and as no good motors of the alternating current type were available, the system lacked in flexibility and general availability, so that its advantages of being able to cover large areas were minimized. The difficulties thus encountered at this stage of the art were first settled in a large way in the electric railway field. The new trolley systems limited at first to small urban districts with a few cars and short run of track began to reach out for the suburbs, while the process of consolidation within urban limits brought large and successive increases of mileage to be energized with electric current from the same plant. The solution of the difficulty of supplying electrical energy in continuous volume over large areas for the propulsion of cars was found to consist in the abandonment of smaller direct current dynamos and their substitution by very large alternating current dynamos, whose current could be transmitted with slight loss for several miles and rectified or converted at substations, which in turn delivered the current to the lines at the voltage required for the operation of the motor. Analogous methods were immediately found to be economical in electric lighting, and the revolution was very quickly accomplished in both fields, the process of transition, however, being accompanied by the abandonment of single phase alternators in favor of the 2-phase, and more particularly the 3-phase type.

One of the modifications of manufacture in nearly all dynamos of this type has been their self excitation and compounding with alternating current. In the earlier practice small direct current machines were employed, driven by separate engines or by turbines to furnish the current in exciting the field of single phase or polyphase alternators. A further step was illustrated in the Niagara plant, where the current for exciting the fields of the generators was obtained directly from synchronous converters, which in turn were supplied with alternating current from the generators—static transformers, however, being interposed to reduce the potential. In this manner alternating current at about 125 volts potential was delivered to the collector of the rotary converter, and from the direct current commutator of the other converter current was delivered at a potential of 175 volts to the generator fields. The next step has been to lead the current generated by the machine directly to the field windings for excitation and compounding by means of a peculiar commutator device. By the interposition and suitable interconnection of transformers, or by certain circuit arrangements in a single transformer, the exciting current of the machine is taken off in shunt to the main winding and the compounding current in wattless series, and so conducted to the commutator that the exciting current remains approximately constant for all loads, while the compounding increases and decreases with the wattless component of the main current. The main feature of the machine is the commutator and the connection of the field windings to it. At the time of this report the self-excitation of the alternators has become a general practice, but their compounding within the machine itself, while regarded as effective, is an expensive process. There are other devices for large alternators which are altogether outside of the machine, and which do not increase the cost of the machine itself.

With the introduction of the steam turbine in place of the reciprocating engine, as will be further noted below, there has come into vogue a new class of dynamo electrical machinery, whose characteristics are determined largely by the fact that the turbine operates at a high speed and thus permits large amounts of power to be produced and handled within a very small space. The dynamos in this class become so much an essential and integral part of the machine that a new name has been coined to designate them and they have become universally known as "turbo-generators." It will be readily understood that where a type of apparatus running at approximately 300 revolutions per minute undergoes a change by which it is operated economically and efficiently at 3,000 revolutions per minute, economic and engineering advantages present themselves, and these will explain the rapid development of the product in the turbo-generator field during the census year. It is significant of the pertinent relations of these advantages to dynamo construction that in the United States the construction of these turbo-generator units has been begun and fostered almost wholly by dynamo electrical manufacturers, and up to the present moment has remained in their hands to such an extent that two or three of the leading steam turbine manufacturers, who also build dynamos, may be said to control the production of certainly not less than 75 per cent of the steam turbine output, whether for dynamo operation or simply for the other purposes to which steam engines have hitherto been applied.

The best illustration of the use of 2-phase alternators is to be found in the power transmission field, particularly at Niagara Falls and on the Pacific coast. The first large utilization of Niagara power was made in a plant of 50,000 horsepower, composed of 10 vertical shaft turbines, each directly connected, by means of a long shaft in the wheel pit, to a 2-phase alternating current generator of 5,000 horsepower capacity. This was supplemented in 1904 by another power house containing 11 generating units of the same type and capacity, affording a total output for the plants of 145,000 electrical horsepower. Each machine is made for generating electrical energy in the condition of 2-phase, 25-cycle current with a potential of 2,300 volts in the machine and operating at a speed of 250 revolutions per minute. In the earlier plants the alternating dynamos were all of the external revolving

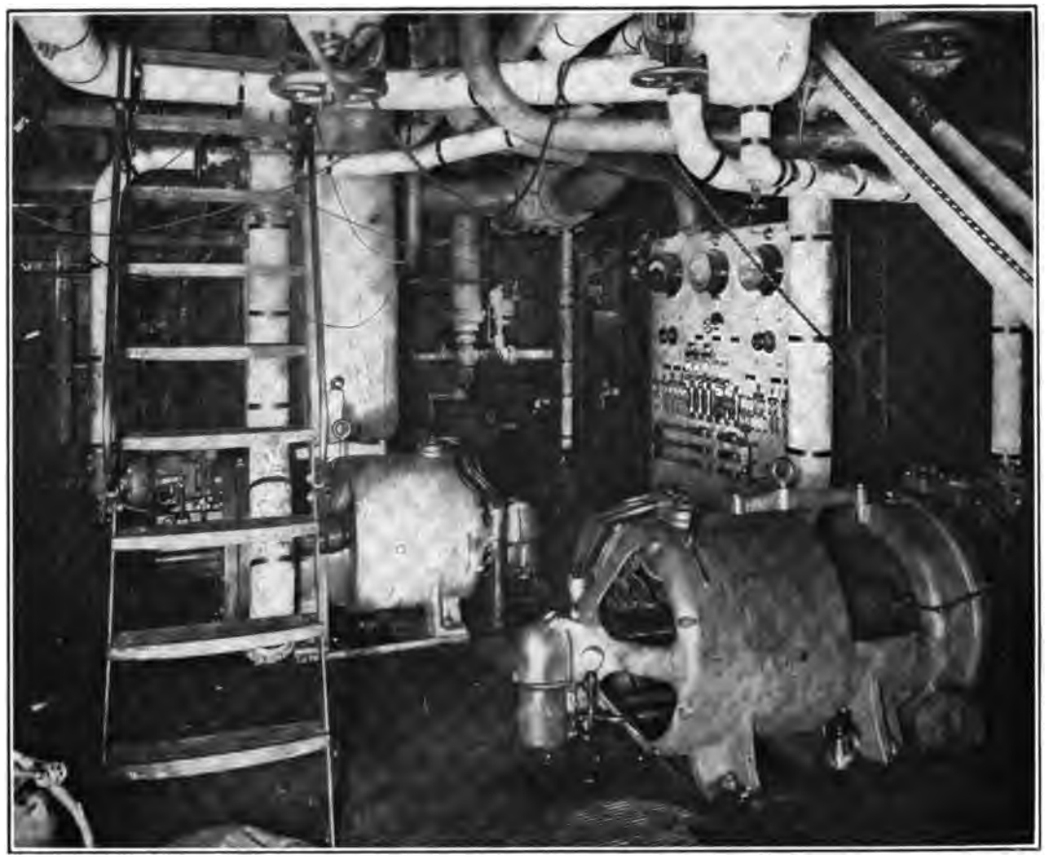
field or umbrella type. In other words, contrary to the ordinary practice of the time, the armatures were made stationary and the field magnets revolved and inclosed the armature. In the second power house several of the machines are of the internal field-magnet construction; that is, the field magnet has been placed within the armature.

The next step was the design and construction in America of even larger apparatus of this type for the development of power on the Canadian side by the Dominion branch of the American corporation known as the Niagara Falls Power Company. The unit adopted for this was of double the size and capacity, namely, 10,000 horsepower, and wound for 12,000 volts 3-phase instead of 2-phase. The rapid advance in the art is shown in the fact that not only was the unit thus doubled in size within a year or two, but the voltage generated within the machine was increased from 2,300 to 12,000, an enormous stride in manufacturing skill. The new 10,000-horsepower unit occupies only slightly more space than that of one of half the capacity, which results, for a given plant output, in great reduction in length of wheel pit, power house, and fore bay, and a consequent reduction in expense of construction of the hydro-electric plant as a whole. This latest type of large generator driven by waterpower is of the internal field vertical shaft type, the turbine being at the lower extreme end of the long shaft in the wheel pit. The revolving field ring is built up of laminations bolted together with lapping joints, a method which gives a uniform and definite strength of ring with a high magnetic permeability. On account of the high speed of 250 revolutions per minute the generator is small compared with some large steam engine driven units, its over-all diameter being only about 19 feet. The weight of the revolving part of the machine, namely, the field magnets, is 141,000 pounds. The change from 2-phase to 3-phase in these later machines was made at Niagara for the reason that in distributing large amounts of power underground from a 2,300-volt 2-phase plant it becomes cheaper to transform, after a radius of about one mile is exceeded, to 12,000-volt 3-phase and distribute at that voltage. Hence it follows that greater economy of plant construction and operation is secured by the employment of these larger units, directly generating the useful current within themselves at the higher voltage and thus dispensing with transformers. It will be understood, of course, that for the delivery of electrical power at such distant places as Buffalo, Rochester, Syracuse, Toronto, etc., long distance step-up transformers are still employed, raising the voltage to 22,000, 40,000, or 60,000 volts.

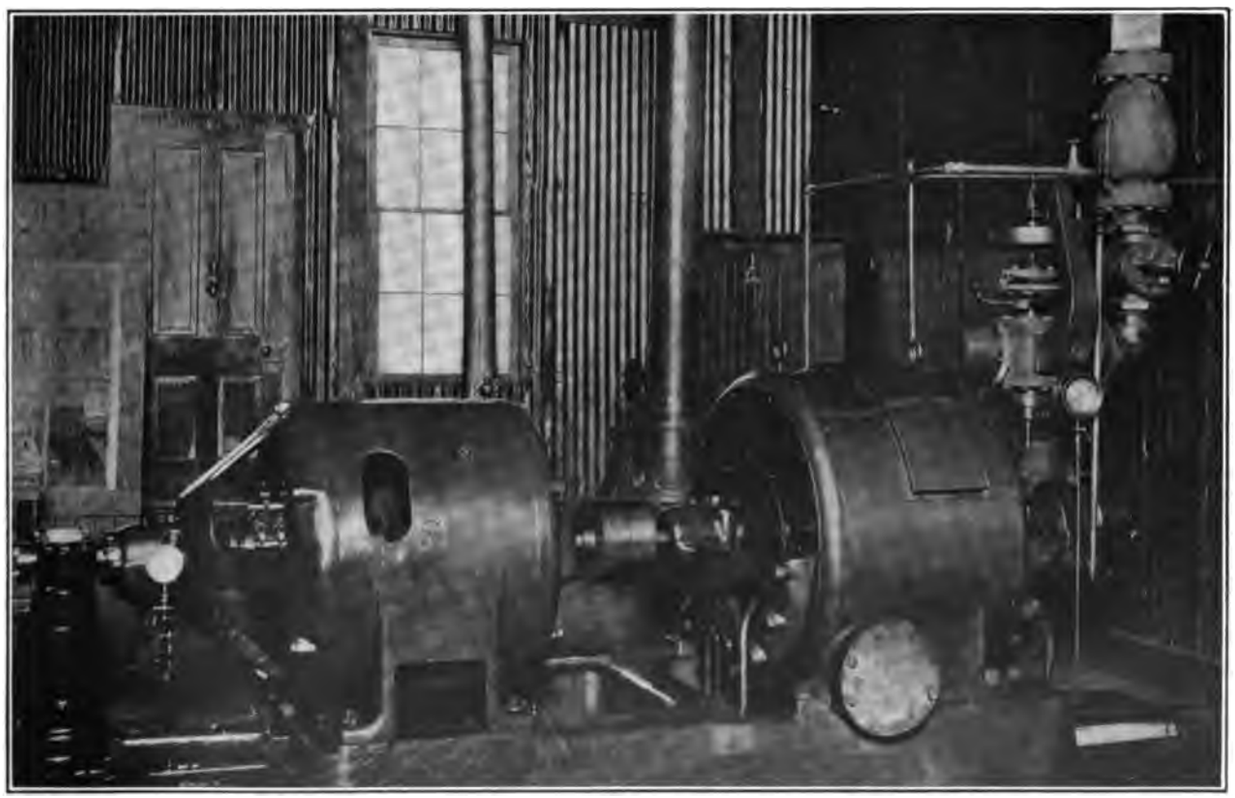
An altogether new departure in dynamo construction has been introduced by the adoption of steam turbines as the prime moving agent, the new practice giving rise to many special problems of a mechanical and electrical nature. Briefly stated, it may be said that the essential feature of a steam turbine consists in a set of nozzles or blades through or against which steam at high pressure passes so as to strike upon another series of angularly placed plates, vanes, or cuts mounted upon a rotating shaft, the whole being inclosed in an outer case or chamber, and the rotating shaft of the turbine carrying the rotor member of the dynamo-electric machine. The arrangement of the turbine or of its parts is such that the steam which has impinged upon a first set of plates or vanes is led through a second set of orifices so as to encounter a second set of plates or vanes during a further expansion, this process being repeated until the steam has virtually lost its useful driving power. The steam in expanding in this manner, adiabatically, acquires a great velocity, the potential energy of its heat being converted into kinetic energy in movement, which is transferred to the device upon which it impinges, so that the potential energy of the steam is converted into work through the rotation of the shaft upon which the receptive plates or vanes are mounted. There is already a variety of constructions of the steam turbine type upon the market, almost all of them designed primarily for the operation of dynamo-electric machines. It is not necessary here to enter into the principles of steam turbine construction, but it is essential to note the main features of the electrical constructions that have resulted from the adoption of the turbine as a prime motor.

Some idea of the extent of the new development may be formed from the fact that during the year ending in April, 1906, the two largest concerns in the American field of dynamo construction received orders to manufacture in one case a total of 188 steam turbines with a total capacity of 220,250 kilowatts, and in the other case 323 turbo-units with an aggregate capacity of 221,175 kilowatts, a total of not less than 441,425 kilowatt capacity. As these were not the only ones produced in the field, it will at once be perceived how enormous a proportion of the addition to the aggregate capacity of American dynamo-electrical machinery the turbo-generators represented in the year of the Census report. The average turbine appears to have been of about 1,000 kilowatt capacity, although the units ran down to as small sizes as 15 kilowatts, or about 20 horsepower.

As already noted, these turbo-generators are of two types, the horizontal and the vertical. In the case of the leading horizontal type made in the United States, the dynamo end of the turbo-generating unit may be said to follow with fair closeness the precedent methods of construction. Two frequencies of current are standard, one of 25 cycles per second for railway and power work, and one of 60 cycles per second for lighting. The character of the generator determines the speed of



STEAM TURBINE GENERATOR SETS IN ENGINE ROOM OF A HUDSON RIVER STEAMBOAT.



TWENTY-FOUR HUNDRED KILOWATT STEAM TURBINE GENERATOR AT A COAL MINE IN KENTUCKY.

the turbine units, and vice versa. For instance, the 25-cycle generator, which at 1,500 revolutions per minute has 2 poles, has 4 poles at 750 revolutions. The generator has a revolving field structure, small in diameter and finished smooth, to minimize windage, ventilation being secured by ducts cut in solid steel. The standard construction of laminated armature is employed and the structure is well ventilated by air ducts between the laminations, to communicate with the interior air by means of slots or openings in the frame. According to the voltage and current capacity of the machine the windings are of wire, bar, or strap copper, and they are thoroughly protected by embedding them in closed slots in the laminations of the armature. The largest types of such machines are exemplified by the 1,250-kilowatt units furnished for the Interborough Rapid Transit plant in New York city. There the horizontal turbo-generator units are of the revolving field type, delivering 3-phase, 60-cycle current directly to the distributing system at a pressure of 11,000 volts. Each unit operates at a speed of 1,200 revolutions per minute, therefore requiring a 6-pole magnetic field. The capacity at full load is 1,250 kilowatts, with 25 per cent steady and 150 per cent intermittent overload capacity. Tests made on these machines show an average efficiency of 96.5 per cent at one and one-fourth full load, 96 per cent at full load, 95 per cent at three-fourths load, 92.7 per cent at one-half load, and 86 per cent at one-fourth load. These efficiencies are calculated from the measured electrical and magnetic losses, the bearing friction and the windage loss not being included. The short-circuit current of the generator is approximately three and one-fourth times the full load current. The generator has been run under test on open circuit for nearly twelve hours at 12,150 volts with full excitation. Under these conditions the maximum rise observed in temperature in the stationary iron of the machine was only 26.7° C. and the rise in the temperature of the field structure was 16.7° C.

The other leading distinctive type of dynamo-electric machine, driven by steam turbine, is vertical instead of horizontal. The leading example of this may be described as a type which, in addition to having nozzles delivering steam at high velocity to a single wheel, has also stationary vanes that redirect the steam which has been discharged from the first wheel into the second wheel. The design of this entire unit, electrically and mechanically considered, has embodied many radical features as compared with other similar apparatus. The shaft, as noted, is vertical and the whole weight of the revolving part is borne in the smaller or earlier designs by an oil film maintained by a pressure pump at the lower bearing. The delivery of steam to the turbine part is controlled through a system of electrically operated individual valves worked by a small controller, a centrifugal governor moving the controller. The revolving field structure of the dynamo is mounted upon the same shaft as the turbine wheels, and above them in the same common casing. The stationary part of the generator is supported by the stationary portion or casing of the turbines, the whole apparatus being built up, in a machine that is rated at 5,000 kilowatts, into the general form of a vertical cylinder about 25 feet high and 14 feet in diameter. The total weight of such a machine complete, including turbine and generator, is 400,000 pounds, with the capacity as stated of 5,000 kilowatts load, and capable of running at about 75 per cent overload condensing, and at nearly full load noncondensing. The first large machine of this type was built for the Chicago Edison Company, and among the latest are those for the New York Edison Company, in which the size has been carried up to 8,000 kilowatts with 50 per cent overload capacity for two hours. This unit at the base is slightly over 15 feet, while the height over the governor dome is 32 feet. The total weight is approximately 700,000 pounds. In accordance with the latest practice of the manufacturers the water type of step bearing is used instead of the oil film type for supporting the weight of the vertical shaft. These turbines are designed to operate under a steam pressure of 175 pounds with 100 degrees of superheat. Their rating permits them to carry a load of 9,000 kilowatts for twenty-four hours of steady running and their overload capacity of 15 per cent, or not less than 16,000 horsepower is guaranteed for two hours as stated. These generators are of the 4-pole type, and operated at a normal speed of 750 revolutions per minute will deliver 3-phase current at a potential of 6,600 volts with a frequency of 25 cycles per second. As will be seen, the leading feature in this latest development is the increase of speed from the 500 revolutions per minute of the earlier 5,000 kilowatt units. With regard to this vertical type of turbo-generator carried up into such large sizes, it is said that compactness and simplicity are resultants of the design, while lateral strain is removed from the bearings which align the shaft, and all deflection of shaft is avoided. To carry such weights as are necessary in the revolving parts of these large units, many very large bearings would be required if the shaft were in a horizontal position. It would also be difficult to so support the wheels that their clearances would not be affected by the sagging of the shaft nor by looseness in the bearings. It might be equally difficult to place the wheels with such a relation to each other that the clearance would not be affected by any expansion of the shaft. In the vertical design the space between the wheels is feasibly reduced to a minimum. The supporting structure is symmetrical and it can not be distorted or put out of line either by the mechanical or steam pressure strains or by the effects of expansion.

Be this as it may, it is the fact that at the period of dynamo-electric construction closing with this report,

the turbo-alternators, whether of the horizontal or the vertical type, had become dominant in the field of the production of electrical energy, whether supplied for street railways, for electric lighting, or for power purposes, and their future preeminence was no longer doubtful except so far as the new and larger types of gas engine may be made an economical and mechanical success in the propulsion of dynamos. For such work, three direct connected dynamos were built during 1905 to be driven by gas engines, each with a capacity of not less than 4,000 kilowatts. These interesting units were built for operation in San Francisco, but their operation and testing has been delayed by the catastrophe which visited that city early in 1906.

Closely associated with dynamos is the group of apparatus comprising double-current generators, dynamotors, motor generators, boosters, and synchronous converters, statistics for which are as follows:

[2] Includes states as follows: Indiana, Kentucky, Maine, Massachusetts, Minnesota, Missouri, New York, Pennsylvania, Texas, Virginia, and Wisconsin.

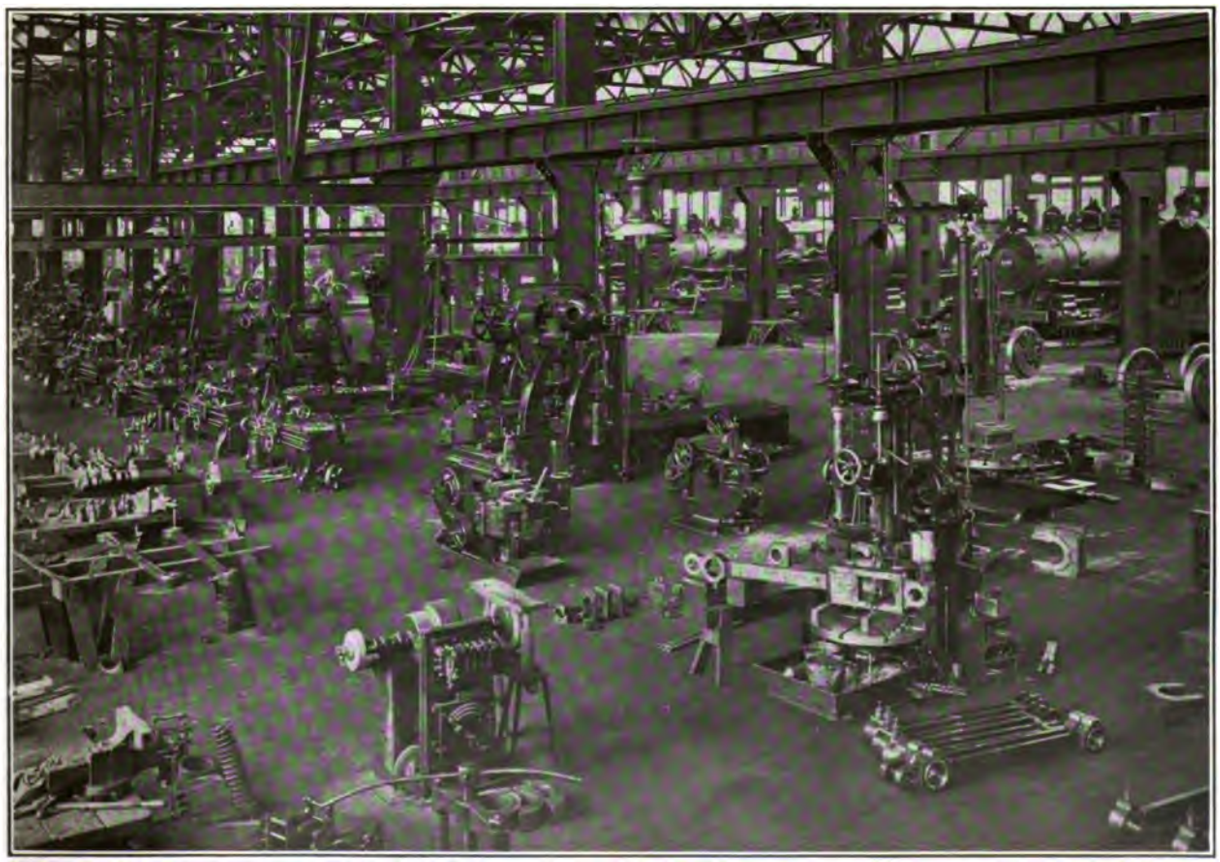
The statistics of Table 4 include 2,135 machines of this type of a total capacity of 279,552 horsepower, valued at $1,740,534, for the census of 1905. All this apparatus embodies the striking characteristics of the generating apparatus by which mechanical energy is converted into electrical energy, but, except in the case of the double current generators, a small and limited group is employed for the manipulation of current so as to render it more readily and economically available in the consumption circuits. As already noted, practically all the 2-phase and 3-phase current generated by the machines enumerated in the preceding paragraphs passes through synchronous converters, by which it is transformed to direct current for charging storage batteries, driving motors, energizing lamps, or setting into operation electro-metallurgical and electro-chemical processes.

The synchronous converter is a dynamo-electric device receiving the alternating current on one side and delivering direct current on the other side, or vice versa. This type of machine is more particularly favored in America than are the motor generators, where the receiving part of the transformer system is a separate machine mounted on the same shaft as the delivering machine, which is connected to the consumption circuits. In the last year or two motor-generator devices of a large type have come into more general use in America, hence some of them are included in these figures. Of course it will be understood that a synchronous converter can be, so to speak, inverted, and the practice is sometimes found to prevail of driving the machine as a direct current motor, taking electrical energy from direct current supply mains through its commutator and delivering this energy in the form of alternating current from its collector rings. These rotary converters are now often built in units of several hundred horsepower and the substations in which they are located are themselves much larger than were the generating plants of a few years ago. In New York city to-day, while there are barely a half dozen large generating plants located at the water's edge, there are scores of these distributing stations scattered all over the city in which the synchronous converters are located; and the same general disposition is true of the extensive power transmission systems and interurban railroads now to be found in so many of the rural and mining districts of the country.

The dynamotor has been quite extensively manufactured for telegraphic purposes. Its principle is that of receiving the current from a general source of supply and then delivering another current from the same machine at the required voltage for any one of the numerous telegraphic circuits, each to be supplied with a different current. In the dynamotor the two armature windings are usually placed upon the same armature core and are acted upon by the same flux magnet. The object of this construction is to secure compactness and enable the armature reaction of the dynamo to neutralize that of the motor, thus avoiding troubles the chief of which is sparking at the commutator. This method has been found open to the objection, however, that it is somewhat difficult to insulate the two windings from each other and to prevent the high voltage in one from breaking through to the other. A further development of the same idea to secure independence of action between the motor and the dynamo portions of the dynamotor or "rotary transformer"—as it is sometimes called—is to carry the separate armature windings upon separate cores and to allow each to be acted upon by its own field magnets, thus permitting the field of the dynamo to be independently regulated in order to vary the voltage that is generated. In some cases the separate armatures are mounted upon the same shaft with one set of bearings and the two machines are arranged upon the same base or bedplate, sometimes with an intermediate bearing, in which differentiation they approach again the motor generators already described.

As a general thing, while there is some looseness of phraseology about the matter, the term "dynamotor" is applied to the smaller transforming units employed in telegraphic work, etc., and the idea of the synchronous converter is associated with the

WINDING ARMATURES FOR ELECTRIC GENERATORS.



RAILROAD SHOP WITH TOOLS EQUIPPED WITH MOTORS ON MULTIPLE VOLTAGE SYSTEM.

kindred machines doing the heavy work of lighting and power.

Double current generators are machines of the synchronous converter class, for since the synchronous converter is provided with a single armature winding connected to a direct current commutator and the alternating current collector rings, it is evident that if such a machine be driven by outside mechanical energy, it can be made to generate both direct and alternating current; and as a matter of fact in some plants such machines are employed as converters at one period and as generators at another time. One early and typical use of such work was furnished in the installation of the Chicago Edison Company a few years ago, when double-current generator units were installed for the purpose of cross-connecting the generating stations, in order to enable one plant of the system to help out another as desired.

[9] Includes states as follows: California, Colorado, Illinois, Indiana, Kentucky, Maine, Massachusetts, Michigan, and Pennsylvania.

Table 5 shows a substantial advance in number and horsepower over the preceding census year, accompanied by a smaller proportionate increase in the total value. As in the case of dynamos, the larger sizes and the greater number produced may be held to explain directly the smaller cost of apparatus to the purchasing public. The extraordinary fact emerges that the value of the motors built was twice as great as that of the dynamos. During the past five or six years, as evidenced by the statistics of power employed in manufactures, the use of electric motors has become almost universal, so that relatively few new mills or factories of any size are established in which the power is not distributed largely by means of electric motors attached directly to the tools or machines, or by short lines of shafting. This change has been facilitated by the general introduction of electric lighting in industrial establishments, so that the same power plant gives forth its electrical energy for the motor by day and for illumination by night. It is interesting to note that no fewer than 79,877 direct and alternating current motors of a total of 678,910

horsepower were built in 1905 for industrial power and kindred motive purposes, with a value of $13,120,948, giving an average size of 8½ horsepower to the motor and an average value of about $19 per horsepower.

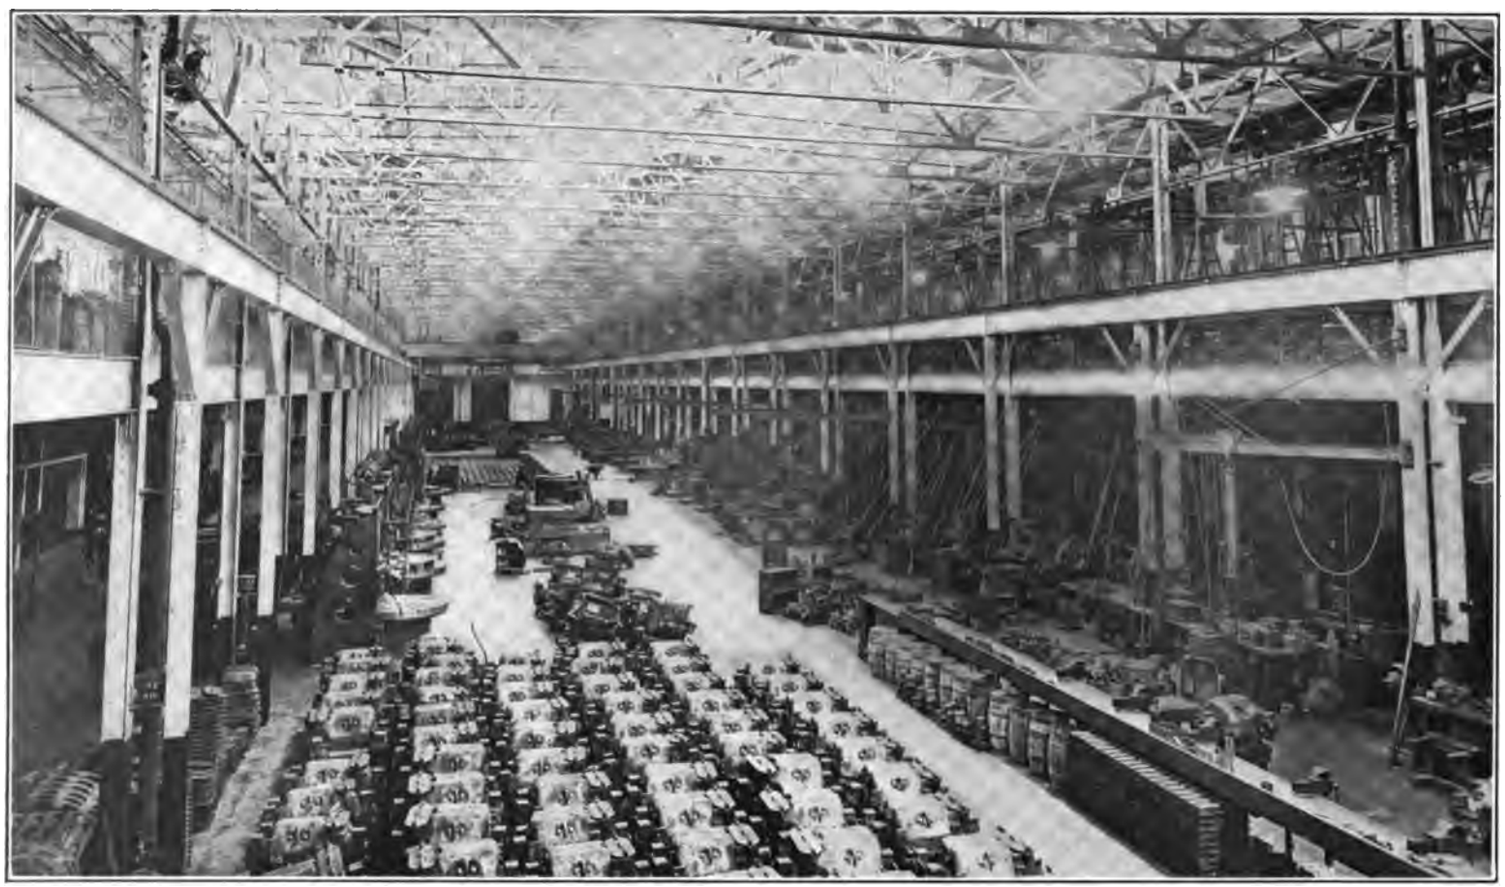
In the street railway field the number of motors required from the manufacturers had actually decreased, being only 12,298, as compared with 15,284 in the year 1900. They had increased, however, in size, but had fallen notably in value, as the capacity was 713,181 horsepower, reported at $4,949,795; whereas in the previous period 666,669 horsepower was returned at a value of $7,568,841—a decline from nearly $11.50 per horsepower to less than $7. This difference was obviously brought about by the gain in size, the railway motors at the census of 1905 having an average size of 58 horsepower as compared with 44 only five years ago. Of course this size is notably exceeded in motors intended for the replacement of steam locomotives, as will be noted below in more detail, but it is also the fact that the larger and longer cars now employed on almost all the electric street railways have necessitated the use of larger motors for their propulsion.

In the automobile field the only serious relative decline is noted with respect to the utilization of electric motors. In 1900 there appeared great likelihood that the electric automobile might advance to perfection as rapidly as other branches of electrical appliances had done, but in general the results have been unsatisfactory, due to the fact that the storage batteries installed have not been able to withstand the excessive jarring and jolting to which they are subjected on uneven roads and poorly paved streets. At the same time even the electric automobile motor has held its own, for while the number is a little more than one-half and the value has decreased considerably, the capacity has increased from 8,220 to 19,907 horsepower. Here again the question of size has had a material influence, and the average capacity of automobile motors has grown from 2½ horsepower to 11 horsepower. This condition is due to the fact that the employment of the electric automobile has very largely shifted from the field of pleasure vehicles to that of industrial types, drays, delivery wagons, etc. Confirmation of this point of view is found in the statement of one manufacturing concern in September, 1905, that in the four years immediately preceding it had built, equipped, and put in operation some 800 electric automobiles for 300 different concerns, nearly all of these machines being intended for industrial purposes.

The electric fan, which has now become a staple electrical product, is shown to have reached over 100,000 a year, valued at more than $1,000,000. As a matter of fact, the type for office use has not varied greatly, being standardized at a fraction of a horsepower. But on the other hand, improved methods of ventilation in theaters, halls, hotels, hospitals, etc., have called for larger sizes, so that while the 97,577 made in the year 1900 had a capacity of only 12,766 horsepower, an average of over one-eighth of 1 horsepower, the 102,535 produced at the census of 1905 had a capacity of 30,796 horsepower, or nearly one-third of 1 horsepower each. Again, it was due to the increase in the size and capacity that the value has been materially reduced. In fact, the electric fan, when regarded upon the horsepower basis, appears to be extravagantly costly as compared with power motors or street railway motors, the average price per horsepower in 1900 having been about $83; but this can readily be accounted for when it is remembered that the average fan motor for desk or countingroom would readily sell at $10 or $12, with a capacity of one-sixth or one-eighth of 1 horsepower. At the census of 1905 the value per horsepower had fallen to much less than half, namely, $38 per horsepower, indicating not only the lower cost of the older, smaller types of fan motor, but the use of a great many ventilating fans of from 2 to 5 horsepower each, so that the prices more closely approximate those for motors of equal rating in other fields of application.

There is no opportunity to compare the relative number and capacity of motors made for electric elevators, as in most cases only the value was given in 1900; but even allowing for an increase in size, it may be questioned whether the decline in value can be accounted for solely upon the supposition of a reduction in price. The electric elevator, which has lately exhibited a spurt of activity, has for some years past had to encounter the opposition of hydraulic and "plunger" types vigorously pushed, and is understood to have barely held its own in the twenty to thirty story buildings now to be found in the larger cities; but there is reason to believe that many of the motors returned under those employed for motive power purposes should have been reported as employed in the elevator and hoisting class, which would have tended to place these figures more upon an equality, with fuller justice to the electric elevator. It is a matter of fact that a large number of new apartment houses in large cities are being equipped with elevators propelled by direct and alternating current motors, and the central station companies report a considerable demand for this class of service.

It should be understood that in both the fan motor and the electric elevator class a large proportion of motors are of the alternating current type, but no differentiation was made in securing the census data. This differentiation would apply equally to the motors enumerated under "miscellaneous." Of these, no fewer than 8,481 were reported for the census of 1905, with a capacity of 36,820 horsepower and a value of $2,340,471. It is to be noted that the motors in this group ranged higher in price per horsepower in 1905 than those in any other category, a fact explained by their small average size and by the variety of their application; spe-



FLOOR OF ELECTRIC FACTORY FOR ASSEMBLING ELECTRIC RAILWAY MOTORS.

cial design and construction being necessary in many instances—as, for example, their use on submarine boats, on board men-of-war for handling ammunition and guns, in exposed places for building operations, in mines for drilling and coal cutting, in post-offices for stamping letters, and in a variety of other uses equally dissimilar and heterogeneous.

The electric motors applied to motive power purposes in industrial establishments are, as the statistics show, of either the alternating or the continuous current type, subdivided again into various groups and classes, determined chiefly by the work to which they are applied. Some motors are designed and supplied to afford constant speed or variable speed and are also compound wound—that is, compounded so as to embody the characteristics of the two other general types. The constant speed motors under normal conditions give practically constant speed for all torques and horsepower capacities within the range of the motors. The synchronous alternating current motors in this group give absolutely constant speed if the cycles or frequencies of current in the circuit upon which they operate remain constant. Continuous current constant speed motors are shunt wound and are usually known by that designation. The alternating current motors in this class, besides being of the synchronous type, are also of the induction type and may be either single phase or polyphase. The induction motor with its absence of commutator has many special advantages and recommendations. The single phase induction motors, included in the figures presented, have generally been built only in the smaller sizes and for operation upon lighting circuits, where the effect of sudden calling for current is not likely to have much if any effect upon the steadiness of the light. When larger induction motors are required, or a large number of small ones, power work is usually done on separate polyphase circuits. One of the difficulties in connection with synchronous motors has been that of making them self-starting, and on account of the low torque developed and the large current taken from the line they have not generally been built of late, although they have been known in the art for several years. The variable speed motor gives automatically great variation in speed for the different torques and horsepower output required of it, and has been found specially suited for work requiring frequent startings and stoppings, such as that in connection with elevators, etc. The compound type of motor is more applicable to work requiring heavy starting torque or frequent startings and reversals, and also for operation at fairly constant speed for great lengths of time. Among the classes of work that may be specified for such motors are the operation of printing presses, machine tools, planers, shapers, etc., where reciprocating motion is desired, the motor being particularly useful in holding back the rush of current from the circuit at the moment of reversal, when the torque required is at a maximum.

During the past few years electric motors of both the alternating and direct or continuous current type have been used to a considerable extent in iron and steel mills and their auxiliary apparatus, and more lately for some of the heaviest operations. Such work includes hoisting, hauling, shears, punches, saws, cross rolls and other rolls, roller beds for slabs, ingots, and blooms, apparatus for pouring steel, horizontal charging machinery for open hearth furnaces, etc. The variable speed motors are used universally for cranes and hauling as well as for the screwing down rolls, charging machinery and the smaller reversible roller beds, while the compound type of motor is also used for the larger roller beds, and for those where the reversals take place less frequently, as well as for the larger saws, cross and straightening rolls, punches, shears, etc. Some idea of the heavy nature of the work now included is afforded by the fact that 1,200 horsepower compound motors were installed recently for the Phoenix Mills to operate the reversing rolls, while two 1,500 horsepower compound wound motors, operating at 100 revolutions per minute and suitable for 25 per cent increase in speed, were ininstalled in the Edgar Thomson Works for rolling rails. A 1,500 horsepower motor was also installed in the Pittsburg Electric Works to drive blooming mills. At one plant in Germany the electrical capacity is of not less than 10,000 horsepower, and the rolls are driven at 120 revolutions per minute, the speed being attained in less than four seconds from the time of starting. The roller train consists of 4 housing frames with rolls of an average diameter of about 29½ inches, turning out blooms, steel rails, and I-beams to a maximum of 17.7 inches in height. These mills have also been turning out blooms from blocks of 2 tons, as well as I-beams 9½ inches high and 164 feet long, and I-beams 13¾ inches high and 82 feet long. In mining operations, partly for deep and speedy hoisting work, motors of equally large capacity have been successfully installed and are now in operation.

Altogether the most remarkable application of electric power in any class of work is that afforded by the new steel works at Gary, Ind., where all the machinery is being installed to be driven electrically, while the gases from the blast furnaces furnish the prime motive power for the operation of the generators. The large rail mill is driven by 3-phase induction motors, ranging in capacity from 2,000 to 6,000 horsepower, attached to the main rolls. These are altogether the largest electric motors in the world. These motors are reversible and are specially controlled, and, being subjected to sudden heavy overloads, each motor is provided with a heavy fly wheel, which, with the system of control, stores up energy when running normally and returns it to the rolls when subjected to heavy overload. Each motor can sustain an overload of 50 per cent for one hour, so that each of three of the motors which has a normal rating of 6,000 horsepower can deliver not less than 9,000 horsepower for one hour if called upon to do

so. In controlling these motors for such extremely heavy and trying service a master controller is used, upon which the main line oil switch can be opened or closed, the reversing switch be thrown in either position, or the resistance cut in and out of the rotor circuit in successive steps by means of electrically operated switches or contactors. Special precautions have been taken to insure the automatic protection of the controller system. It is impossible to operate the reversing switch unless the main line switch has been previously opened, and if the main line switch has been opened by the overload trip, it can not be closed without first bringing the controller to the off position. With regard to the special arrangement of the fly wheel in restoring energy to the motor, so-called "slip relays" are provided, in which the actuating coil carries the current to the motor. Whenever the motors are subjected to overloads the slip relays operate, cutting a small portion of the resistance into each phase of the rotor circuit, causing the motor to slow down gradually and the fly wheel to give up a portion of its energy. When the load is taken off the motor, the reverse operation takes place and the motor speeds up, returning the energy to the fly wheel.

Another large field of application of power motors is exemplified by printing offices, where not only the presses but a large number of auxiliary appliances are thus driven. The most conspicuous example of the kind in the United States is afforded by the Government Printing Office in Washington, where about 700 motors, varying in size from one-sixth of 1 to 100 horsepower, have already been utilized for the operation of the two-revolution presses, job presses, stitching machines, shaving and beveling machines, electrotype finishing apparatus, card routing machines, molding presses, and a host of other apparatus required in the processes of the printing art. Mr. W. H. Tapley, the electrician of the establishment, in discussing the equipment, has remarked: "The advantage to be gained from changing over from belted steam driving to individual electric motor for printing-press work is not alone in power saved, but better grade of work, less spoiled sheets, cleaner, healthier rooms for employees, less repairs to machinery, and most of all, an increased product without a corresponding decrease in value of the presses by running at too high speed. There has never been a hitch in the motive power; not a motor has given out. In fact, such a freedom from interruption of power has never been known in the history of the office."

A new type of small motor, which has come into considerable use since the last report for industrial motive-power purposes, is that known generically as the "interpole," which, while essentially a variable-speed motor, can also be used for constant speed work. It is manufactured specially for driving machine tools, pumps, woodworking machinery, laundry machinery, and similar classes of apparatus, whether directly connected or in belted groups. These motors operate on any 2-wire direct current lines at pressures of from 110 to 500 volts. The principle of manufacture in this motor is that of placing auxiliary field pole pieces, small as compared with the main pole pieces, and located between the latter, in the circular ring composing the field. These small pole pieces are provided with coils connected in series with each other and in series with the armature coils, and are so proportioned and arranged as to give the proper field for commutation. This construction enables the brushes to be placed equidistant between the poles; and the motor is capable of reversing its direction of rotation without detriment; and commutation in either direction of rotation takes place without sparking, whether the motor is running with variable load or at variable speed. Since the main current flows through the auxiliary field, weakening of the commutation fringe by an increased load is prevented, and the auxiliary poles produce the compensatory field of commutation independently of the main fields, which with increasing number of revolutions of the armature must be correspondingly weakened. The effect of the auxiliary pole is also independent of the direction of the rotation of the armature, because if the latter is reversed the current in the auxiliary field coils is also reversed. The absence of sparking is a great desideratum, especially where high voltages are employed, and it is this fact which has pointed to the adoption of the motors of the inter-pole type for direct current traction at higher voltages than have been employed hitherto in America. The ordinary direct current railway motor operates on a potential of 500 to 600 volts, whereas the inter-pole types can be employed up to 1,200 or 1,500. In the meantime a large number have already gone into use in mills and factories and machine shops.

The development of the electric railway field has provided, as the statistics show, an extraordinarily large and profitable opportunity to the manufacturers of street railway motors. Strange as it may appear, however, the production of this class of apparatus is confined in reality to three or four factories, and the amount of work done by one of these is relatively insignificant. There is, however, a large class of kindred work devoted to the requirements of mining, for which a considerable number of small electric locomotives are constructed annually. But even this did not materially enlarge the area of manufacture, so that at the most there are not ten factories where street railway motors and electric locomotive motors are built, although the value amounts to almost $5,000,000 a year. Whether the centers of production will remain thus limited in number as the conversion of steam railroads to electrical operation advances, presents an interesting industrial problem, especially as it has been the practice of many steam railway systems to build their own

locomotives; and should they continue to do this the creation or enlargement of the shops of electrical manufacturers devoted to this class of work would necessarily be checked. In the modern period embracing especially the electrical régime, namely, from 1890 up to 1902, the number of the street cars had increased in this country, as shown by the census figures, from 32,000 to 66,000. Not only has the number of cars increased, but the carrying capacity has increased, necessitating heavier equipment for the motor cars, and involving in a great many instances the use of four motors instead of the two that were standard in the earlier types of cars. The extreme exemplification of this tendency is found naturally on the interurban roads, and on the elevated and subway systems of the large cities. On large interurban systems it is not unusual to find cars 60 feet in length, weighing from 40 to 60 tons, and four-motor equipments may be said to be universal. To take one district as typical, it may be noted that while 75-horsepower motors are a standard type on the interurban railways of Ohio, the cars of the Lake Shore Electric System have each four 85-horsepower motors, while those of the Scioto Valley have gone so far as to adopt 100-horsepower motors. On the Interborough Subway System in New York, where the express trains have a maximum speed of 45 miles an hour, the motor cars carry two motors of 200 horsepower each, both motors mounted on the same truck—that is, the motor trucks are at one end of the cars, two motors and gear to each axle, while the truck at the other end of the car is a trailer and carries no motive power equipment. These cars, whether built of wood or of steel, are 51 feet long, with seating capacity for 52 passengers.

The latest development in the field of street railway motor construction embraced within the period of this report is the resort to alternating current with the single phase motor, or with motors of this type which can be operated both by the direct current and the alternating current, thus enabling them to fulfill more nicely the best conditions of operation at slow speed and low voltage within city limits, and high speed and high voltage in suburban and rural districts of the same system. The advances in this field have been very rapid, and to such a degree that while a number of street railways have been equipped with this style of apparatus, the New York, New Haven, and Hartford Railroad has gone further and has installed it for use on its first electric zone, having New York as the terminus or center. One of the latest and best exemplifications of single phase motor work is furnished by the Pittsburg and Butler Railway, with a circuit distance of not less than 40 miles, with heavy grades involving an average rise of 8.5 per cent continuously in lengths of 1,100 feet, and with several 7-degree curves, over which grades and curves a schedule speed of 25 miles an hour is maintained. The single phase cars of this road are each provided with four 100-horsepower motors of the compensated type, designed for using both direct and alternating current, so that while using the direct current within the city limits of Pittsburg and Butler, they "let themselves out," so to speak, with the alternating current on the intervening stretch. In these motors the field coils are placed in slots in the cylindrical laminated pole structure, and the compensating coils are distributed over the total pole area. Thus the compensating coils are in a position to neutralize effectively the magneto-motive force of the armature current, while the field coils are in proper mechanical position to allow of the best production of magnetization in the projecting field poles. The field coils of each motor are connected electrically in series, and this connection is not changed at any stage of the operation. The four motors are operated two in parallel, by two in series, for alternating current, while they are connected permanently two in series for direct current operation. Each car is provided with a frame-like skeleton pantagraph type of overhead trolley for picking up the alternating current, and with two ordinary wheel trolleys for direct current work.

In main line operation, such as that involved in the system of the New York, New Haven, and Hartford Railroad for the section between New York and Stamford, Conn., a much heavier type of single phase motor equipment has been required. The total distance is 33 miles, and between the New York suburb of Woodlawn and Stamford the road is equipped with single phase alternating current locomotives taking current from an overhead line. For this electrification 35 locomotives have been ordered. Each locomotive is furnished with 4 motors, each of 250 horsepower nominal capacity. These are of the gearless type and are wound for a normal speed of 225 revolutions per minute. They are connected permanently in pairs and require about 450 volts at the terminals on alternating current and 550 volts on direct current. The frame of each motor is split horizontally, so that it can be removed in halves in order to give access to the interior. In the floor of the cab is an air conduit, from which air is pumped to each motor in such a way as to keep it clean and cool, and this method of cooling enhances the capacity of the motor to such an extent that the rating at continuous operation is almost as good as at the one-hour rating.

On the direct-current part of the line current is taken from a third-rail system with overhead sections at short cross-overs, with the four shoes on each side of the locomotive arranged in pairs of two each. These contact shoes for direct current are ingeniously contrived to work on both forms of third rail, namely, that in which the shoe runs on top of the rail and that in which it makes an underneath or upward contact. The locomotive is also provided with a pantagraph low-tension overhead trolley, and for connecting with

the alternating current has two pantagraph type, high tension bow trolleys. Each trolley has a sufficient capacity to carry the total line current under average conditions, but two are provided to insure reserve safety capacity. For alternating current operation 11,000 volts are applied directly to the overhead line, carried by steel bridges over the track, and two step-down transformers on the car lower this pressure to the 450 volts required for the operation of the motors. Each of these locomotives handles a 200-ton train in local service on a schedule of 26 miles, with stops averaging 2 miles apart, and in order to maintain this average speed the maximum speed is about 45 miles. One locomotive is able to handle a 250-ton train on through service—that is, with infrequent stops—while for heavier trains it is the practice to couple two locomotives together and operate them in multiple.

The New York Central and Hudson River Railroad has equipped its New York terminal for operation with electric motors for a distance of not less than 34 miles out on the main line from the Grand Central station to Croton, and for 24 miles out on the Harlem division. At the entrance to this electric zone all steam locomotives are dropped, so far as passenger and mail traffic is concerned, and these trains are handled by electric locomotives of the heavy high speed express type, and in the suburban service by individual motor cars. The first contract was placed for not less than 50 electric locomotives, each of which is capable of making regularly in forty-four minutes without a stop the trip from the Grand Central station to Croton, a distance of 34 miles, with a total train weight of 435 tons. The heaviest of these through trains, weighing 875 tons, is drawn by two of the locomotives at a maximum speed of from 60 to 65 miles an hour, but recently upon test attaining over 80 miles. The locomotive has, broadly, the main lines of the steam locomotive and has four driving axles, on each of which is mounted the armature of a direct current electric motor of 550 horsepower, so that the total rated capacity of the locomotive as a unit is 2,200 horsepower, although for short periods considerably greater power may be developed, making it far more powerful than the largest steam locomotives now in existence. The weight of the locomotive is 97 tons. It has eight driving wheels and four truck wheels, a driving-wheel base of 13 feet, and a total wheel base of 27 feet, the driving wheels being 44 inches and the wheels of the engine truck 36 inches. The maximum tractive drawbar pull is 34,000 pounds, and the tractive pull per ton of engine weight is 330 pounds. The length over the buffer platform is 37 feet, the extreme width 10 feet, the height to the top of the cab 14 feet 4 inches, and the diameter of the driving axles 8½ inches. The voltage of current supplied is 600 volts and the normal full-load current is 3,050 amperes.

These motors mark a distinct advance in electric locomotive construction and have the armature built directly upon the axles. The advantage of direct application of power to the driving axles is thus secured, avoiding the losses in gear and pinion which are encountered in ordinary railway motors employed in street railway work, which have a single reduction between the armature and the car axle. There are only two pole pieces, which are thus practically part of the truck frame, and have flat vertical faces. There is no necessity, therefore, for maintaining a rigid alignment between the field and the armature, and the armature can have a large free vertical movement without danger of striking the pole pieces. The larger part of the weight of the motor, consisting of its field structure and frame, is carried upon the journal box springs outside of the driving wheels. The dead weight on each driving axle is practically the same as on an ordinary steam locomotive, and is said to be about 10 per cent less than that on the heaviest types, while in addition there is no unbalanced weight to produce vibration, which is injurious to track and roadbed construction. The main frame of the locomotive is of cast steel and the field poles and windings are arranged in tandem, the end pole pieces being cast as part of the end frames and the double pole pieces between the armatures being carried by heavy steel transoms bolted to the side frame, and forming part of the magnetic circuit as well as cross braces for the truck. The field coils are wound upon metal spools which are bolted upon the pole pieces. The superstructure to the motors and their truck frame consists of a central cab for the operator or motorman, containing the multiple unit control system, engineer's valves for the air brake system, and the switches and valves for sanding the track, whistling, bell ringing, etc. In this cab is also placed an electric motor driven air compressor, which is automatically cut in and out of circuit when the air pressure falls below 125 pounds or exceeds 135 pounds.

Current is carried from a third rail placed alongside the track by means of multiple-contact, spring-actuated, third-rail shoes, the support of these shoes being carried on channel irons attached to the journal box. Four of these shoes are placed on each side of the locomotive. In the yards at the terminal the large number of switches and crossings necessitates an overhead construction in places, and additional contacts, somewhat after the trolley system, are therefore mounted on the top of the locomotive for collecting current when the locomotive is passing these points. Another type of third-rail shoe, so hooded and protected as not to be dangerous to life nor exposed to accidental contact with falling metal of any kind, has been devised by engineers of the system.

For the enormous suburban traffic handled over the New York Central lines the company has built an initial equipment of 125 steel motor cars, the suburban traffic being brought into the Grand Central station at one level and the heavy traffic with the electric locomotives at another level. These cars are made up into trains of the motor cars and trail cars, as are those on the New York Subway and on the modern electric elevated roads of New York, Chicago, Boston, etc. During the period of initial operation under the electrical régime these cars are coupled up for part of their run for haulage behind steam locomotives. The motor equipment of these 125 motor cars comprises two motors for each car. These machines are rated at 200 horsepower each and both motors are mounted on the same truck. They are operated at a potential of 650 volts, although this can be carried up to 750 volts. The motor trucks are all steel, with 36-inch wheels on the motor trucks and 33-inch wheels on the trailer trucks. The total weight of the motor car loaded is 111,560 pounds, and the weight of the motor per truck is 12,400 pounds. It may be of interest to note that a steam train of the average suburban type with locomotive and six loaded cars weighs 700,160 pounds, while the electric train of equal seating capacity with four motor cars and two trailers weighs 621,360 pounds, or a difference of 39.4 tons in favor of the electric train.

Transformers.—Table 6 shows the production of transformers reported in 1900 and 1905.

[1] Includes transformers to the value of $2,700, for which number and horsepower were not reported.
[2] Not reported separately.
[3] Included in "all other states."
[4] Includes states as follows: Illinois, Massachusetts, Missouri, New Jersey, New York, Ohio, Pennsylvania, and Wisconsin.
[5] Includes states as follows: Massachusetts, Missouri, New Hampshire, New Jersey, and Pennsylvania.

The production of transformers has nearly doubled from one census to the other, the value having risen from $2,962,871 to $4,468,567, while the total capacity has increased from 407,451 to 970,908 horsepower, and the number from 36,513 to 66,698. These statistics are eloquent testimony to the growing use of alternating current for lighting and power purposes, particularly for lighting in large suburban and semirural districts and for substation purposes in the large railway systems and in most of the large cities. So far as lighting is concerned, the cities of the first class which began originally with lighting systems based on direct current supplied to their customers are still dependent on that type of current, but the operating companies have adopted generation by means of alternating current dynamos, sending out their current at high voltage to substations where it is lowered in pressure by transformers and converted for delivery to the consumption mains. It will be seen from the statistics that more than half the capacity of the transformers manufactured in the census year, namely, 504,009 horsepower, was comprised in transformers of 50 kilowatt capacity and upward, giving an average of nearly 150 horsepower. The effect of size on price is seen in the fact that these larger transformers were returned as valued at $1,176,360, or slightly over $2 per horsepower, a low figure as compared with the price of those under 50 kilowatt capacity. In this latter class, of which there were 63,311, the total capacity was reported as 466,899 horsepower, valued at $3,292,207, or about $7 per horsepower. It is also to be noticed that the average size of these smaller transformers was under 10 horsepower. Taking the figures as a total, it seems that the average value of all transformers in 1905 was about $4.50 per horsepower; whereas in the previous census year, 1900, the average value returned for the total output was slightly over $7.25 per horsepower. This fact emphasizes the effect of the larger size in reducing the cost to the purchaser, but the general reduction is not so clearly determined, for the reason that in the earlier census a differentiation into the two classes was not made between large and small transformers.

As already remarked, these statistics indicate a large production and the important place filled by the transformer in the arts of furnishing light, power, and traction. There are no figures available for the production in the intervening years between 1900 and 1905, and no attempt is made in the present report to distinguish between transformers employed for lighting stations and for power for electric railways, as many of them serve both purposes at the same time. But it is significant that the capacity of the output reported in 1905, namely,

970,908 horsepower, was much larger than the total capacity of the transformers manufactured in 1900. If those of larger capacity than 50 kilowatts be excluded in 1905—as that class would embrace all of those devoted to traction purposes, while probably none in the smaller class was so employed—it is to be noted that in 1905 the capacity was not less than 466,889 horsepower, while, expressed in the same unit of power, the total capacity of all transformers five years before was only 407,451 horsepower. A little further light on this relation as to the use between the larger and the smaller transformers is also given by the Census report of 1902 on lighting plants, where it is shown that the transformers in substations as a part of the central station distributing system had a total capacity of 419,367 horsepower, or nearly one-half as much capacity as all those manufactured in 1905. All the evidence, therefore, that can be brought to bear upon the subject shows that the electric lighting art claims a very large proportion of the transformers manufactured, both as to capacity and number.

The smaller transformers are mainly of the same type as those which were included in the report of 1900 with improvements rendering them more strictly weatherproof; while in the larger sizes it has become the practice to keep them cool by means of immersing the working parts in oil, so that the transformer is virtually an oil tank, containing the primary and secondary coils. In some instances the cooling is also effected by means of air, for which purpose forced draft is occasionally resorted to. The oil is found a better heat conducting medium than air, and a transformer will show a much lower temperature with oil cooling than without. Hence its use is very general through a large range of sizes.

Owing to the development of alternating current power transmission, which has rendered desirable and necessary a corresponding increase in both the kilowatt capacity and the voltage pressure of the transformer units, some of the latest transformers are of sizes that a few years ago would have been considered gigantic. These transformers are used both for stepping-up the electromotive force to a value suitable for transmission economically, and for stepping it down again to safe pressures at the receiving consumption ends. There are several types of these larger transformers. One type, which may be presented as typical, has the oil within it set into continuous circulation by the cooling effect of water coils placed in the top of the transformer tank, to which the oil transfers the heat generated in the transformer. The oil rises through ducts provided in the iron and copper structure of the transformer, giving up its heat to the water coils and descending between the transformer and the wall of the tank. The entire circulation of oil thus effected secures a high cooling efficiency of the oil in the transformer. The largest units of this type built up to the date of the figures of this report were 2,670 kilowatt capacity each, transforming 25-cycle single phase current from 10,000 or 12,000 volts up to 50,000 or 60,000 volts in connection with the utilization of Niagara Falls. A much larger type of transformer, however, is that in which the use of a pump and reservoir in the oil circulation system gives a better control of oil circulation in the transformer so that the heat, which can be easily held down to safe and economical limits of temperature, rises for continuous full load operation; while with sufficient capacity in the oil and water pumps such transformers can carry extreme overloads in the hour of emergency. The oil is circulated by pressure and the water by suction, so that any leak developed in the circulation system does not result in the admixture of the water and the oil. The largest transformers of this type have been those built for the Great Northern Power Company in connection with the development of the St. Louis river in the vicinity of Duluth and have a capacity of not less than 7,500 kilowatts on 25-cycle 3-phase current, and can actually carry 10,000 kilowatts. In these huge transformers the low tension windings are adapted for 6,600 or 13,200 volts, while the high tension windings will withstand 30,000 or 60,000 volts. These transformers have the exterior dimensions as follows: 14 feet 10 inches high, 14 feet long, and 5 feet 10 inches wide.

Switchboards.—Table 7 presents the statistics of switchboards as reported in 1900 and 1905.

TABLE 7.—*Switchboards for light and power—value: 1905 and 1900.*

STATE.	Value.
United States, 1905	$3,766,044
1900	1,846,624
States, 1905:

Wisconsin	11,075
All other states [1]	227,532

[1] Includes states as follows: Connecticut, Delaware, District of Columbia, Georgia, Louisiana, Maine, Maryland, Michigan, Nebraska, New Jersey, North Carolina, Oregon, Rhode Island, Texas, Washington, and West Virginia.

This section of the report is devoted specifically to switchboards intended for electric light and power and electric railway work. It will be understood that there is no system of centralized electrical supply to-day that does not depend upon a switchboard for the manipulation of the circuits—that is, for the connection of the sources of supply with the customer; but this grouping does not include telegraphic or telephonic switchboards, which are included in their respective categories and which are employed for the work of placing the operators or the persons communicating in immediate and direct relationship with each other. With

switchboards for light and power the ultimate consumer is not a factor of the problem, whereas in telegraph and telephone boards every circuit of the individual operator or of the individual telephone subscriber must be led to the board in order to permit of the instantaneous and direct interconnection, and this may be said to constitute the great line of differentiation.

As will be seen from the statistics, the value of the lighting and power switchboards has risen from $1,846,624 in 1900 to $3,766,044 in 1905. In other words, the product has almost doubled in the period. This fact, however, does not emphasize fully the importance that the switchboard has assumed in modern installations, for the reason that the board has ceased to be a unit and has in a general way become subdivided, so that in large plants it often extends over several floors, its various parts and mechanisms being placed one above the other. This kind of construction has been called for by the prevailing method of generating electrical energy in the form of 2-phase and 3-phase alternating current for transmission at high voltages to substations, where it is converted into direct current, and there, through the intermediary of the subswitchboards, passes out to the consumption circuits. In the Government Printing Office at Washington is an excellent type of the old style of direct current switchboard, built of Tennessee marble and having a total length of over 83 feet. The new section of this board, with a length of 34 feet, consists of two generator panels and seven feeder panels, carrying not less than 25,000 pounds of copper on its circuits to receive and distribute the current from the generators. This board, which represents an expenditure of several thousand dollars, is bound by handsome, heavy copper molding, with iron framework and angle iron braces, cable carriers, etc., and is heavily coated with asphalt paint for insulation. It will be noted that marble is used, and this, with slate, is the prevalent material. Wood, which was at one time universally used even on boards for currents of high voltage, is now severely discriminated against in the rules of the National Electrical Code.

A recent type of the "straightaway" switchboard for alternating current purposes is furnished in the equipment of the Holyoke (Mass.) Water Power Company, where the long board, all on one floor, is made up of 12 panels, of which 6 are generators, 2 are exciters, 3 are feeders, and 1 is a regulator, while 3 are left blank for extension. The 6 panels equipped with the apparatus for controlling the generators are furnished with push-button switches for the control of the water-wheel governors, the plant being driven by water turbines as well as by steam turbines. By means of this push-button system of control the switchboard attendant is enabled to raise or lower the speed of the water wheel, and hence that of the alternating generator, which is to be thrown into the supply system in parallel, by merely placing his finger on one or both of the push buttons and without removing his eyes from the synchronizing lamp that indicates the proper moment for completing the operation. A more brilliant and striking exemplification of the push-button control in switchboard practice is afforded by the "dummy" type of board which has been installed in several plants and is to be found in some of the largest stations, such as those of the Manhattan and Interborough Railway systems in New York city. The switchboard proper is associated with a control board with which every alternating generator switch, selector switch, group switch, and feeder switch upon the main floor is represented by a small switch connected into a control circuit receiving its supply of electrical energy at 110 volts from a small motor generator set and storage battery. The motors which actuate the large oil switches upon the main floor of the power house are driven by this 110-volt control current, and thus in the hands of the operator the control switches make or break the relatively feeble control currents, these in turn, after the manner of relays, closing or opening the switches in the main power circuits. The control switches are grouped upon the control bench board in conjunction with dummy bus bars and other connections, so that the whole constitutes at all times a correct diagram of existing connections of the main power switches. Thus every time the operator changes a connection by opening or closing one of the main switches, he changes necessarily the diagram before him on the dummy board so that it represents the new conditions that have been established in connection with each control switch. Small bull's-eye lamps are used like signals—one colored red to indicate that the corresponding main switch is closed, and the other green to indicate that it is open. These little lamps are lighted when the moving part of the main switch reaches approximately the end of its travel. If for any reason the movement of the control switch should fail to actuate the main switch, the indicating lamps would not be lighted. The control board is divided into two parts; one for the connection of the alternators to the bus bars, and the other for the connection of the feeders to the bus bars. Such arrangements have simplified and assisted greatly the work of the switchboard attendant, but can not be said to have lessened in any degree the length, or size, or complications of the main switchboard system.

A good idea of what may be called the distributed switchboard may be gained from the electrical control equipment installed in the Waterside stations of the New York Edison Company, where, on the first floor level, adjacent to the steam turbine room in Plant No. 2 are located the exciter units and associated controlling apparatus, a booster, a compensator, and two end-cell switches for the storage batteries. On

the first mezzanine floor are the main and auxiliary bus bars, encased in compartments of brick wall and concrete cement, the bus having wired glass doors in front and at the back, where the cables are attached through disconnecting switches. The second mezzanine gallery contains the selector oil switches by which the feeder or generator cables are connected to the copper bus bars or "busses." On the third mezzanine gallery are the potential transformers, whose connections are brought down from the gallery above through disconnecting switches. On the fourth mezzanine floor are the oil switches, from which are led out through series transformers the high tension feeders to the underground mains. On the fifth mezzanine gallery are placed racks to carry the control wires to the operating boards. Hence it will be seen that the switchboard or switching mechanism continues through several floors or tiers of the building and presents a front to the dynamo room far exceeding in height that of an ordinary dwelling house. The view of such a lofty switchboard as seen in the Waterside Plant No. 1 is indeed most impressive, and gives a vivid idea of the enormous equipment and expense necessary for merely handling the currents generated in such enormous volume by the large power houses.

At one time the switchboard industry was carried on by a large number of manufacturers and required little else than skillful working in hard wood. At the present time switchboards, such as those described, with their huge slabs of slate or marble, and their framework of copper, iron, and steel, involve many problems of intercommunication and of apparatus adjustment. The result is that the larger electrical manufacturing companies have virtually taken over the construction of the switchboards for the plants which they equip, and have made a business also of supplying many of the indicating and recording instruments placed upon the front of the boards.

Batteries.—Table 8 presents statistics of storage and primary batteries, parts, and supplies for 1900 and 1905.

TABLE 8.—BATTERIES, STORAGE AND PRIMARY—VALUE: 1905 AND 1900.

[8] Includes states as follows: California, Connecticut, Maryland, Massachusetts, Michigan, Ohio, Oregon, Pennsylvania, and Rhode Island.
[9] Includes states as follows: California, Connecticut, Illinois, New Jersey, Ohio, Pennsylvania, Rhode Island, and Texas.
[10] Includes states as follows: Connecticut, Illinois, Massachusetts, New Jersey, and Pennsylvania.

The returns from manufacturers as to the production of primary and storage batteries, parts, and supplies give a total of $4,243,893, as compared with $3,679,045 at the previous census. Of this total in 1905, storage batteries contributed $2,645,749 and primary batteries $1,598,144. As a matter of fact, the total that should be credited to this field would be larger if it were possible to include within it several items which are necessarily thrown into "all other products." Both storage and primary batteries consist of various elements, which are not always distinguishable or sold together as a unit by the same manufacturer, and yet it is not until these are brought together that a complete cell is constituted. In fact, many of the parts and supplies lie outside the electrical field. For example, a storage battery complete consists of lead plates, the separators used between them, the sulphuric acid solution into which the plates are immersed, and the containing jar of glass, porcelain, rubber, etc. The primary battery in like manner consists of various elements, such as the jars, zinc, copper, carbon, sulphuric acid, caustic soda, bichromate of potassium, according to the nature of the cell, and on the constant renewals of these the efficiency and life of the cell depends. There has undoubtedly been a very large increase in the production and use of storage batteries since the census of 1900, but it is not revealed to any extent by the relative figures here presented. It is true that in the year 1900 there was great activity in the department of storage battery automobiles, giving a stimulus to the production of batteries for that purpose; but while the demand in that field has not fulfilled expectations it has grown enormously in other branches of the electrical arts, and to meet

it there have been extensions of the factories devoted to this line of manufacture.

The most extensive use of storage batteries, as already indicated, is in connection with central station lighting plants and electric railways. In such a system, for example, as that of the New York Edison Company storage batteries are to be found not only at the substations but also at the generating plant. In the new Waterside Station No. 2 of that company there are two large batteries installed in the basement, one of 140 cells and the other of 150 cells. One of these is kept on the exciting system for the excitation of the alternating current generators and the other is at all times available for the local distributing system. In like manner, for the work of the New York Central Railroad, the electric storage battery equipment is the largest of its kind in the world. It not only takes care of the fluctuations in the load, but is sufficiently large to operate the entire system under normal conditions for a period of one hour, in case of failure of the generating apparatus. Five of the batteries have an output of from 2,000 to 2,500 amperes for one hour, and the three others have outputs of 3,000, 3,750, and 4,020 amperes, respectively. The batteries are located in buildings adjoining the substations, and are operated in connection with the booster and switching apparatus which occupies the substations. The discharge from the battery is governed by a carbon regulator working in connection with the exciters and boosters, the aim and object of which is to make the battery discharge when there is a heavy demand for current from the line and to charge when the demand is so light that the generating plant can economically put its surplus into this reserve.

The use of large storage batteries, employed to improve the reliability of the railway systems as well as to reduce the operating costs, is well illustrated by the interurban roads of Indiana and Ohio. They have usually been installed with enough lead plates to meet the demands of the load at the time of initial equipment. The large tanks which contain the electrolyte in which the plates are immersed, the boosters, and the other accessories are, however, often considerably larger, so that as the load grows, plates can be added to the battery, and the additional work can be adequately taken care of. In Ohio there are 25 such installations and at least 16 in Indiana, making a total of over 40 large storage battery equipments in these two states in interurban railway work alone. They aggregate 9,376 kilowatts at a one-hour rate of discharge, and when increased to their ultimate energy capacity will have an aggregate of 11,710 kilowatt hours. The function of the battery in such work is indicated by the example of the Northern Ohio Traction and Light Company, which has a battery of 195 kilowatts initial capacity and 288 kilowatts ultimate capacity. Before the installation of this equipment it was necessary at all times to operate two 250 kilowatt generators to carry the load and operate the cars. After the battery was installed it was found feasible to operate the load a large part of the time with only one generator, resulting in a large saving of coal. In like manner another battery of 140 kilowatts has been operated on the Ravenna division to assist in maintaining a steady electrical pressure on the line, so that whereas the electromotive force formerly fluctuated between 100 and 500 volts, it is now maintained at a minimum of 400 volts with much greater efficiency in the operation of the cars. The Dayton and Northern Traction Company was a pioneer in Ohio in the use of the storage battery for interurban work and at two substations has batteries, each of which consists of 260 kilowatts capacity. This road was especially laid out with a view to the use of the battery as an auxiliary, and was therefore enabled to install smaller generators and rotary converters than would have been possible had the battery been omitted.

The storage batteries mentioned above are almost wholly of the lead-lead type or those using lead or lead compound as the active material on the plates and diluted sulphuric acid as the electrolyte in which the plates are dipped or submerged. These lead batteries are made in various ways, but are of two generic types, the Faure and the Plante, the former type predominating as that in which the slower forming process of the Plante method is obviated.

A second class of storage battery little known or used is the copper-zinc or lead-zinc type, but a third class of which considerable numbers were made in the census year is that due to Edison in this country and Jungner in Sweden, in which the soluble zinc negative of the lead-zinc battery is replaced by a grid containing an insoluble metallic sponge. Caustic potash solution is employed as the electrolyte. Upon discharge the metallic sponge becomes oxidized, while the metallic oxide on the positive plate becomes reduced; on discharging the original condition is reproduced.

With his aim directed at very exacting requirements, Mr. Edison has made a large number of iron-nickel cells. The structural material of the cell is steel. The grids and cups that support the active material, the connecting and binding posts, the spacing washers, nuts, jars, and cover are all made of thin steel. In fact, the entire cell is constructed of steel, with the exception of the small amount of hard rubber used for insulating purposes. Each piece employed in the construction of the cell is plated before using with a heavy coat of nickel, which is fused to the steel by a special process, adding to the durability and finish of the cell. The active materials, consisting of specially prepared oxides of nickel and iron, are packed into very finely perforated cups or pockets in the plates, each cup or pocket being made in two sections engaging one within the

other. To preserve contact between the particles of active material at all times so as to secure the maximum electro-chemical effect, the nickel mass has been admixed with a considerable amount of graphite in the form of excessively thin flakes and the iron mass has been admixed with a small portion of mercury. These added materials act simply as insoluble conductors between the active particles. When filled with the active material these light cups are placed in suitable rectangular openings in the thin steel grid, and the whole being subjected to a very high pressure, the two sections of each cup are firmly locked together and are at the same time fastened securely into the grid, then resembling somewhat the panes of glass in a small window or the slats in a shutter. The result of this method of manufacture is a plate extremely strong mechanically yet one of unusual lightness. To the eye there is no difference between one of the plates packed with nickel oxide and one built up with the iron oxide cups. In the ordinary type of cell there are 24 of the cups in each plate, and the cell consists of 28 such plates, 14 of nickel, connected with the positive pole of the cell, and 14 of iron oxide, connected with the negative pole, each set being strung on a connecting rod, and all of them being interlocked in such a manner that each iron plate has a nickel plate on either side of it, and each nickel plate has two iron plates as neighbors, except in case of the end plates, one of which is of nickel and the other of iron. The outer surfaces of these plates are in juxtaposition, with two sheets of hard rubber serving to insulate the metal plates from contact with the sides of the containing steel jar. The iron and nickel plates are also prevented, by separators, from coming in contact, for which purpose hard rubber rods have been used. It will be understood that cells can be made with a lesser or larger area, this being simply a detail of manufacture to meet the requirements. The outer jar is made of corrugated sheet steel, having pieces of hard rubber at the bottom and ends to protect it from contact with the plates. The cover is welded to the jar, and on it are mounted two stuffing boxes through which the binding posts, fastened to the positive and negative elements of the cell, extend. There are two other small mountings on the cover. One is the separator which separates the spray from the gases when the battery is charged, thus preventing loss of potash and causing the gas to be inodorous. The other is the filler, through which the electrolyte—a 20 per cent solution of potash—can be supplied to the cell and through which distilled water may be added from time to time to maintain the level of the electrolyte, offsetting the loss by evaporation and overcharging. This filler has a water-tight cover held in place by a strong catch. Fastened to this cover is a small spring which causes it to fly open when the catch is released, but it can not be closed again without some small pressure being exerted, nor will it stay closed unless the catch is securely fastened. When the cover is in place, it is always water-tight, and the chances are minimized of leaving it open accidentally and of possible spilling of solution should the cells be severely agitated. These cells are convenient and simply assembled into trays so as to constitute a battery, wooden trays being built to hold four, five, and six cells. The connections between the cells are made by means of heavy copper wire, well nickel plated. This type of battery to the number of several thousand cells was in use at the time of the collection of these figures, but has been subjected to various improvements. One of the great difficulties encountered by Mr. Edison in the development of this battery was to preserve the contact between the nickel particles which alternately expanded and contracted during the charging and discharging operations, resulting in the gradual deterioration in the capacity of the nickel elements. Furthermore, it was found that contrary to the general expectation graphite was not absolutely insoluble to the potash solution when subjected to the effect of electrolysis. To overcome these defects, it is proposed to make the pockets of the nickel mass in the form of small perforated steel tubes in which the material will be packed under a pressure of several thousand pounds per square inch, and to substitute for the graphite, flakes of cobalt or nickel. In this way expansion of the mass is actually resisted by the tubular pocket and consequently the initial contact is indefinitely preserved. The advantages claimed for this general type of "oxygen lift" battery are its greater capacity per unit weight and its longer life, but, on the other hand, objection is made to its low electromotive force of only 1 to 1.25 volts, as compared with the 2 volts and upward of the lead-lead type.

Of late years there has been little change in the primary battery manufacturing field, the reason being that such batteries were not found suited for relatively heavy work, and that in many instances, as in telegraph offices and telephone exchanges, they have been replaced by small dynamo-electric outfits, and by storage batteries. One branch, however, in which there has been marked activity during the past five years has been that of dry batteries. These are in universal use in connection with gasoline or hydrocarbon automobiles, and almost every automobile of that type carries with it an equipment of several dry batteries. These, being under constant use and subject to accidents of various kinds, are frequently renewed, with the result that the production has been very sharply stimulated by the development of the automobile. A primary type of battery that answers many of the purposes of light power, as, for example, driving a fan motor, supplying current to an X-ray outfit, or operating railway signals, is the Edison copper oxide, which, according to Professor Carhart, has a capacity of work per unit weight greater than that of any other

battery, either primary or secondary, hitherto known. In other words, 2.2 pounds of its own weight is able to furnish an amount of electrical energy which, if converted into mechanical energy in a perfect electric motor, would be capable of lifting a pound weight 188,000 feet. In this battery the copper oxide employed is furnished in the form of a compressed slab, which with the connecting copper support serves also as the negative plate. In more recent cells of this type the device has been resorted to of reducing a superficial film of copper on the oxide slab before it is sent from the factory. This film of copper also serves to reduce the internal resistance. The other element in the battery is zinc, the solution being caustic soda.

Prof. F. B. Crocker, in a paper read in 1888 before the American Institute of Electrical Engineers on the "Possibilities and limitations of chemical generators of electricity," discussed and compared the various types of primary cells then on the market, and said that little or no progress had been made for almost a half century, but that the apparatus was at fault rather than the chemical action. He has recently directed attention, as a marked advance in the art, to the battery of Mr. F. A. Decker, of Philadelphia, which has been developed during the past two or three years, and regards it as removing the reproach against inventive ability in this field. This cell is of the two-fluid type, with zinc plates immersed in dilute sulphuric acid and graphite plates in a solution of sodium bichromate and sulphuric acid commingled. The size and number of plates employed in each cell depend upon the current required, but ordinarily there are only two or three flat zinc plates about 5½ inches wide by 9½ inches high, each weighing about 1 pound. Each zinc plate and the dilute sulphuric acid surrounding it are contained in a flat, rectangular, porous cup, made by two unglazed earthenware plates with thickened edges and diagonally strengthened ribs shaped separately in steel molds. These plates are made extra thick to prevent warping in burning, and to produce true flat surfaces and straight edges. When united the cup is ground down on each surface to such an extent that the finished walls are thin and translucent. At the same time the cup is quite strong, no breakages occurring even in automobile service. The exceeding thinness of the walls tends to reduce the internal resistance to a minimum, and the fact that these walls are true permits the graphite and the zinc plate to be placed close together with obvious effect in reduction of resistance, which by test is only 0.013 ohm for a cell with two zinc and three graphite plates and all the connections, the resistance of the plates themselves being included. The negative plates are of graphite, corrugated so as to afford large surface for the action of the depolarizing liquid, with stiffening in the thick edges and diagonal ribs. The case around the porous cups and the graphite plates is filled with the depolarizer, consisting of a solution of sodium bichromate mixed with sulphuric acid. Passing over minor details of construction and finish, it may be stated that a cell of this type under test by Professor Crocker with two zinc and three graphite plates was discharged for a period of five and a half hours at 24 amperes, the internal potential falling from 1.9 to 1.3 volts. In other words, the cell gave 126 ampere hours at an average voltage of 1.73, or 218 watt hours. The cell was then shaken to stir up the liquid and gave 24 amperes for fifty-three minutes longer. This corresponds to the conditions that would exist in electric vehicles, electric launches, or in train lighting. The total output, therefore, was 147 ampere hours at 1.684 average voltage, or 247.55 watt hours. As the complete cell weighed 16.14 pounds, including all solutions, connections, etc., the output was thus 14.7 watt hours per pound of total weight, or about twice as great as that obtained from standard types of the storage battery. The liquid constituted only about one-half of the total weight of the battery, so that with an automobile an additional quantity of solution equal to the weight of the battery could easily be carried in tanks. In this case three times as much electrical energy could be obtained with only twice the total weight. In other words, the output would be 22.5 watt hours per pound, or about three times that obtainable from a standard storage battery. The question of cost is, however, a serious one, and the weight of the zinc, sulphuric acid, and sodium bichromate required to give 1 horsepower hour in this battery—assuming all materials to be thrown away after using—would cost about 35 cents, which is admittedly high. On the other hand, the depreciation of the automobile storage battery is very high, and a close comparison would not be unfavorable to the primary type. An advantage also of this battery, as compared with those of the Edison-Lalande copper oxide type, is its voltage, namely, 1.9 initial and 1.7 average, as compared with 0.667 to 0.4. It is evident from these statements that hope is by no means abandoned in the primary battery field and that the industry has taken on a new lease of life.

Carbons.—Table 9 presents statistics for carbons for 1900 and 1905.

TABLE 9.—*Carbons—value: 1905 and 1900.*

STATE.	Total value.	Lighting (value).	Furnace (value).	Brushes, battery, and miscellaneous (value).

[3] Includes states as follows: Ohio and Pennsylvania.
[4] Includes states as follows: Illinois, Massachusetts, Missouri, New Jersey, New York, and Pennsylvania.

The value of all classes of carbons reported in 1905 was $2,710,935, a gain of almost $1,000,000 over the census year 1900. This gain was almost wholly in the class of "brushes, battery, and miscellaneous," there being, as a matter of fact, a falling off of over $200,000 in the department of arc lamp carbons, in which the amount was only $1,050,971 as compared with $1,263,732 at the census of 1900. Although the amount was small, there was also a very marked gain in carbons for electric furnaces, the total being $172,454 as compared with $10,974, an increase of more than fourteen-fold. Probably no other department of electrical work reported quite so high a gain.

The falling off in arc lamp carbons is not at all due to the smaller production of arc lamps, as the number of these has been steadily maintained; but whereas the old type of open arc lamp required to be supplied daily with new carbon points, the modern types of inclosed arc lamp, which have almost entirely replaced the open type, will burn for a couple of weeks without recarboning, the consumption being so much less in the semivacuum provided by the inner globe of the inclosed lamp. On the other hand, the carbons used in inclosed lamps are of special construction and cost more than the grades usually employed for open lamps, so that the decline in quantity has been to some extent made up by the increase in quality and cost.

Moreover, the past few years have seen the introduction of lamps in which a special kind of carbon stick is necessary. In the ordinary arc lamp employing plain carbons the light of the arc is a bluish white which is often condemned as disagreeable, and, with the object of securing a light which would correspond more closely in color with that of the incandescent lamp and of the gas flame, resort has been made to what are known as impregnated carbons, in which the carbon base has been mixed with metallic salts. The result is that a large number of "flaming" or "luminous" arc lamps are now upon the market and can be seen on the streets of many cities, their light being of a bright golden color. It has been claimed that such lamps can furnish at least five times the light per watt of electrical power as the inclosed arc, but one of the objections has been that the carbons have a tendency to smoke or fume. It is said that in practice it has been found impossible to increase the metallic impregnation of carbon for the flaming arcs above 6 per cent, as beyond that limit the light is no longer steady. For the positive carbon, such metals as calcium, magnesium, barium, etc., are found suitable; while for the negative carbon, metals which form acids are required, such as tungsten, chromium, and molybdenum. Suitable additions in the positive carbon also are fluorspar and magnesia, and for the negative carbons, tungstic acid and chromium fluoride. The diameter of such carbons can be increased so as to increase the life, as they are constructed in several zones or layers, with the mineral admixtures in varying proportions.

Yet another variety of lamp now coming in of the luminous arc type is the magnetite, to which reference has elsewhere been made under "arc lamps," but which may be noted here because it dispenses entirely with carbon. The negative electrode is a stick of magnetite, while the positive electrode is a block of copper.

With regard to the furnace carbons it may be said that these are of considerable size, shape, and variety, depending upon the work required of them. Reference to these in detail can be found in the standard works on electro-metallurgy and electro-chemistry, although details are not usually given of the exact method of use or the extent of consumption. Each year sees some new branch of electro-metallurgical work open up in which such carbon electrodes are used, and it has recently been noted, with regard to the production of pig iron from electric furnaces in Canada, that the consumption of carbon electrodes per ton of pig iron runs between 15 and 20 pounds to the ton, representing, it is stated, an average cost or consumption of 30 cents worth of carbon per ton of the pig metal.

The miscellaneous group of carbons, shown in Table 9, necessarily includes a large amount of other carbons of special shape employed for retort purposes, but there are two other large classes, one including the small carbon buttons and granules used for telephonic transmitters, while the other comprises the carbon brushes now used very largely for all classes of dynamos and motors and invariably for the motors used in electric railway work. Carbons are also used to some extent in electrical resistances, and these are likewise included in the miscellaneous group. In other words, the use of the carbon is universal throughout the electrical arts, ranging from tiny grains up to rods 60 inches in length and blocks well-nigh a foot in diameter.

Arc lamps and searchlights.—Table 10 shows the number and value of open and inclosed arc lamps for 1900 and 1905.

[3] Includes states as follows: Illinois, Massachusetts, New Jersey, New York, Ohio, Rhode Island, West Virginia, and Wisconsin.

The total production of arc lamps reported in 1905 amounted to a value of $1,574,422, or $253,349 less than for 1900. At the same time the number showed a large increase, rising from a total of 158,187 to 195,157. These lamps were divided into two groups, open and inclosed, and since the year 1900 a remarkable change has taken place in the relative importance of these two types. In this short period the production of open lamps fell from 23,656, worth $276,481, to 1,748, valued at $29,989. This number would barely take care of renewals, and hence it may be said that the open arc lamp, with which the great bulk of electric street lighting has been done for so many years, is in process of extinction and may be in a very few years obsolete. This view is corroborated by the fact that the number of inclosed lamps made in one year has risen from 134,531 in 1900 to 193,409 in 1905, and, as will be seen, the larger number has brought with it a reduction in cost. The smaller number in the year 1900 was valued at $1,551,290 as compared with $1,544,433 in 1905. The average cost per lamp is thus reduced from $11.50 each to $8, or nearly one-third. This is very convincing evidence of the popularity of the inclosed arc as compared with its predecessor.

These open and inclosed lamps are of either the direct or the alternating current type. The vogue of the inclosed type dates back to 1894, although experiments upon it began several years previously. The principal element in its perfection consists in the relation of the inner globe to the arc, whereby with a suitably restricted air inlet a long arc may be steadily maintained by a small current. In the ordinary open arc lamp the carbon pencils, or sticks, burn away in ten or twelve hours, but in an inclosed lamp the cored carbons used will last from sixty to a hundred and twenty-five hours. The small inner globe inclosing them is of elongated oval shape and made of refractory glass, so as to resist successfully the intense heat of the arc. The consumption of carbon in the arc in this inner globe fills it with carbon monoxide and carbon dioxide, and as the globe is virtually air tight the prolongation of life in the carbon is due to the fact that little or no fresh air is admitted to help in the consumption of carbons. Moreover, the presence of carbon monoxide and carbon dioxide in the bulb shortens the arc to a length of three-tenths of an inch, and allows a pressure of 80 volts to be used; but although the pressure is thus increased to almost twice that of the earlier type, the consumption of power is not greater, as only half the current strength is required. These lamps have become popular with the public, because of their soft and steady light and brilliant appearance, and with central station managers, for the reason that as the carbons last so much longer the lamps need trimming only once a week and often only once a fortnight, depending upon the hours of nightly burning.

The latest development in arc lighting involves what is practically a reversion to the open arc, and the results are so striking that while the old open arc with its simple carbons may disappear entirely, the supremacy of the inclosed arc is likely to be seriously challenged by the flaming or luminous arc. The efficiency of light production is greater from incandescent gases than from solids, while amorphous carbon such as that used in the old carbon points is inefficient from the standpoint of light radiation. Hence if earth or metal having higher light radiating properties can be combined with carbon so as to become light giving in the arc, a high efficiency would result in the arc lamp using such impregnated carbons. The idea of introducing substances for the arc of higher radiating power than carbon was patented as far back as 1876, while experiments on the subject were made at least thirty years earlier. One of the first practical workers in this field in recent years was Hugo Bremer, of Germany, whose lamps were first brought to this country about four years ago and were employed in New York city. The principal feature of this lamp has been the employment of a compound carbon, the arrangement of carbons at an acute angle to each other, the use of a metal chamber above the arc for reflecting the light downward, and the employment of a magnetic field for the automatic regulation of the arc. In this lamp the carbons are forwarded or focused by gravity. When the arc lengthens to or near the breaking point as the "carbon" burns away, and thus makes it difficult for the arc to sustain itself, an electro-magnetically operated lever, used also to "strike" the arc when the lamp starts into operation, reestablishes the arc, and by its motion enables the electrode to feed until the arc reaches its normal length. Both the electrodes are of small diameter; the positive carbon being about five-sixteenths inch and the negative carbon about one-quarter inch. The negative carbon electrode is an ordinary solid carbon of the kind used in standard arc lamps, but the positive electrode is a cored carbon of special composition—that is, it contains metallic salts in considerable quantities, such as magnesium and boron. These two electrodes are inclined toward each other at an acute angle, and the points are surrounded by a metal chamber open below, like an umbrella. The magnesium in the positive carbon makes a snow-like deposit on the surface of this reflector, this white providing additional highly reflecting surface. The coating obtained in this way adheres to the metallic reflector surface to the thickness of about one-eighth inch. A simple arrangement is employed to obtain the magnetic field for the control of the arc, its strength being dependent upon the current flowing through the lamp, which gives an automatic character to the magnetic regulation. The color of the light is varied at will by the use of proper metallic salts, etc., and is

usually of a clear golden hue. The general principle of such lamps is that, on becoming heated by the passage of current, the salts which have been introduced into the carbon are volatilized and rendered incandescent. The hot gases thus generated furnish a path for the passage of the current of less resistance than the air.

The Bremer lamp has also been made with carbons vertical to each other as in the ordinary arc lamp. This is also true of the Blondel arc, in which only one of the carbons is impregnated with salts for increasing the illumination. The upper carbon is surrounded by a reflector, and the positive lower impregnated carbon consists of three parts—a core and two concentric layers around it. The outside layer is pure carbon; the middle and thickest layer is a mixture of carbon and salts, such as those of calcium, magnesium, etc.; while the central core has the same composition but is less compressed. The object of this arrangement is that the arc shall always remain in the center of the carbon and the carbon shall burn off uniformly. The thickness of the carbon varies with the size of the lamps. In the upper carbon, which with direct current is the negative one, the impregnation is very slight, and consists almost entirely of pure carbon. The vapors from the salt in the lower carbon rise into the arc and are heated to white heat and condensed on the reflector at the top of the lamp. The reflector consists of a central circular reflecting disk of insulated material and an external ring of metal. The Blondel lamps were first made for a current of 5 amperes or 3 amperes, but there is a later type which consumes only 1 ampere. These lamps burn normally on 50 volt circuits.

The flaming arc lamps as a class may be said to operate single on 55 to 65 volt circuits, or two in series on 110 to 120 volt circuits, and four in series on 220 to 240 volt circuits, on either direct or alternating current. The "carbons" burn from eight to fifteen hours, and are said to consume 0.163 watts per hemispherical candlepower in lamps of good efficiency. Some lamps have been used in this country which employ 17-hour carbons, but it will be seen that all such lamps, like the old open type of pure carbon arc lamps, are subject to the disadvantage of more frequent trimming than the inclosed arcs, necessitating the constant attendance of linemen and trimmers.

The magnetite arc lamp, like the "flaming" arc, has already gone into considerable use on street circuits. Its negative electrode consists of a stick of magnetite, while its positive electrode is simply a copper block. This lamp burns for one hundred and fifty hours, or as long as an inclosed arc lamp, but without necessitating an inner globe, while the production of light for 300 watts electrical power is rated as equivalent to that of the ordinary arc at 450 watts. The objection raised to this lamp, as to the others of the flaming arc type, has been the smoky deposit. The statement is made that pure magnetite, while fulfilling the requirements of a carrier of the arc flame, consumes rather quickly, and it has therefore had incorporated with it small quantities of substances, such as titanium compounds, for increasing the efficiency and steadiness of the arc and the life of the electrode. In the manufacture of these electrodes a greater density and longer life are secured by partially reducing the material to metal. Another method of improving the electrode is that of adding a "restrainer" or a substance which reduces the rate of consumption. A simple and satisfactory form of electrode is that in which the material is pressed as impalpable powder into a thin iron tube, which is then sealed over by the arc. In the ordinary carbon arc lamp the light comes from the incandescent crater of the positive carbon on direct current and not from the arc flame, whereas in the magnetite arcs, which are also operated on direct current, no light issues from the terminals but comes entirely from the arc flame; and hence an arc length of from $\frac{3}{4}$ to $1\frac{1}{8}$ inches has been found most efficient. The feeding mechanism differs from the "floating system" of the carbon arc lamp and is much simpler, involving a feeding device to maintain constant arc length. In the magnetite arc lamp, therefore, when the electrical pressure is applied to the lamp, the arc is struck, and the electrodes are separated to a definite distance, say, $\frac{1}{8}$ inch. The electrodes are then locked in this position and remain fixed until, by the slow consumption of the negative electrode, the arc length and thereby the arc voltage has increased sufficiently to operate the feeding mechanism, which resets the arc to its original proper length. An instance of work done with the magnetite lamp is afforded by Portland, Oreg., where after trying 800 lamps for several months the installation was increased to 1,200, these lamps, moreover, being operated by direct current obtained through mercury arc rectifiers to which alternating current is delivered at a pressure of 18,000 volts. These rectifiers will be referred to elsewhere. The magnetite arc lamps in use in Portland consume 320 watts in the lamp in place of 500 watts in the carbon arcs employed before, and obtain for 364 watts of transmitted power the same illumination that originally required 806 watts. This involves a saving of not less than 1,768 kilowatt hours per lamp per year. The cost of attendance on these lamps has been a little less than on the old direct current open arcs which they displaced, and the difficulties have gradually disappeared from operation. The outages that were noticed at first were due to the magnetite sticks. A button of hard glazed slag would form on the end of the stick and act as an effective insulator. The magnetite electrodes were made by the process of packing the magnetite powder or compound into an iron sheath or cylinder, as noted above. This was done at first by hand, with the result that it was uneven, and the slag formed when the sticks were packed too firmly. Machine

packing has, however, been adopted and this difficulty has practically been eliminated.

One further innovation in arc lamp practice is the introduction of lamps in which smaller carbons are used, the lamps having been tried with success in Chicago. It is claimed that there is a marked increase in the amount of light obtained from a given quantity of power as well as a whiter light. The light is steadier, as the arc can not wander so easily around the crater. The size of the carbon adopted is $\frac{5}{16}$ inch. On a 3.5-ampere lamp the use of $\frac{5}{16}$-inch carbons, as compared with the usual $\frac{1}{2}$-inch carbons, gives a consumption of 2.2 watts per candle, as against 3.4 watts with the $\frac{1}{2}$-inch carbons, or an increase of 50 per cent in light. It is necessary to change the lamps slightly to use the smaller carbons, and this is done in the local company's repair department. The gain in steadiness and efficiency is found to be of much importance, especially in meeting the competition of gas arc lamps. The company is now obtaining a life of about one hundred hours from the $\frac{5}{16}$-inch carbons. The smaller carbons do not blacken the inner globe as much as the larger carbons. With large carbons it was necessary, in order to secure good efficiency, to clean the inner globes every seventy hours, or once between each trimming. It is now unnecessary to clean between trimmings. The increase of efficiency by the use of smaller carbons, as well as the greater steadiness and improved color of the light, due to the fact that there is not such a preponderance of violet rays, are matters upon which laboratory tests are hardly necessary, as they are apparent even to the casual observer. Before $\frac{5}{16}$-inch carbons were made the company's standard, the matter was exhaustively tested. Some alternating current arc lamps have also been equipped and put in service with $\frac{5}{16}$-inch carbons, with great improvement in the illumination. Small arc lamps of this general type have also been tried in Germany, within the past year, with the object of closing the gap between the standard arc and the ordinary incandescent.

In the group of arc lamps must be included searchlights and projectors. Table 11 shows statistics of this type of lighting devices for 1900 and 1905.

TABLE 11.—*Searchlights and projectors—number and value: 1905 and 1900.*

STATE.	Number.	Value.
United States, 1905	1,924	$114,796
1900	8,283	225,635
States, 1905:		
California	490	16,147
New York	1,050	47,267
All other states [1]	384	51,381

[1] Includes states as follows: Colorado, Illinois, Indiana, Michigan, New Jersey, Ohio, Pennsylvania, and Wisconsin.

According to the table the number had decreased 77 per cent, while the value had decreased about one-half. On the face of it there would appear to be a serious decline in this class of production since the year 1900, but there are some reasons which would indicate the existence of conditions of a nature more satisfactory to the manufacturers. As will be seen, the average cost per searchlight had risen in the period from $27 to $60, but this is in reality due to an increase in the size and capacity of the searchlight. It is now some years since searchlights were found a desirable and necessary adjunct on board steamships of all sizes, with the result that practically all vessels of American register have been equipped with them. The field of consumption having been thus filled up, practically the only market that is left is the annual accessions to the merchant marine, and it will be seen that 1,924 searchlights would probably take care of all the additions to the steamship fleets of the United States. The merchant marine and the additions to the Navy are practically the only outlets for the manufacturers of searchlights, and the figures quoted indicate that the market has been well taken care of, the other searchlights not accounted for thus being required chiefly for renewals or for ships not previously equipped. This group would also include probably some larger focusing lamps of the kind used for theatrical purposes; but these again have not been treated separately and are very often merely large arc lamps of the ordinary type.

Incandescent lamps.—Table 12 shows the number and value of incandescent, and decorative and miniature lamps, etc., for 1900 and 1905.

One of the largest specialized departments of electrical production is that of incandescent lighting. The gain in this branch since the year 1900 has been quite remarkable, the total value rising from $3,515,118 to $6,953,205, so that the amount has almost doubled in the period. The principal gain as to quantity and value has notably been in 16-candlepower lamps, which remain the standard, although there are indications that it is likely to be raised, owing to the competition of gas of higher candlepower than was common when the incandescent lamp was introduced. The number of incandescent lamps of 16 candlepower has risen from 21,191,131 to 83,333,285, and the value has nearly doubled, but it will be seen from the table that there has been a remarkable reduction in value per lamp, so that these lamps reach the consumer at a retail price proportionately reduced. Lamps below 16 candlepower in illuminating capacity are used to an increasing extent for various purposes, and the number increased from 2,906,817 to 19,779,834, or more than fivefold. The value rose from $308,626 to $1,132,011. In like manner there was a remarkable increase in the number and value of the lamps above 16 candlepower, these being principally 32 and 50 candlepower. The number increased from 1,222,250 to 9,598,439, the gain being almost sevenfold. The increase in decorative and miniature lamps, etc., is not so great as might have been expected from the prevalence of street signs, but the increase was from 397,432 to 1,584,495, with a correspondingly large increase in the value. As a matter of fact, a large proportion of lamps below 16 candlepower are employed for decorative and sign purposes. It is only in the group of decorative and miniature lamps that an increase in price per unit is shown, but this is due to the attempts to place at the disposal of the public very small lamps of ingenious design and construction for special effects. In reality, the product throughout the group as a whole shows a remarkable reduction in cost, the more noteworthy in view of the fact that during the past five years nearly fifty manufacturers have allied themselves under the protection of certain patents, standardizing their methods of production and quality of output. This combination does not constitute a monopoly, as there are also a large number of independent manufacturers.

The importance of the incandescent lamp in the field of electrical industry is evidenced by the fact that, as shown by the statistics of the Bureau of the Census in the Report on Central Electric Light and Power Stations, out of a total of 3,620 private and municipal stations enumerated in 1902 no fewer than 3,484 were engaged in commercial or other private incandescent lighting, while 606 private and municipal plants reported that they were engaged exclusively in the business of incandescent lighting. Further evidence as to the importance of the incandescent lamp was given by the fact that of the total income of all stations of $85,700,605 more than half—$44,657,102—was derived from incandescent service. It is true that during recent years the supply of electrical energy for motive-power purposes from central stations has gained rapidly, but in view of the enormous increase in the production of incandescent lamps it would appear that the proportion of income from light thus exhibited has at least been maintained, and when compared with the income from arc lighting may be said to have increased. In view of these points, it will be readily understood that among manufacturers as well as among central station managers and the owners of isolated plants there has been seen an extraordinary demand for improvements in the manufacture of incandescent lamps, resulting in the last five years in an outburst of research and invention in this field that changed its aspect entirely. The use of the electric street sign has also had a very marked effect on the production of incandescent lamps, and the result of an inquiry made by one of the central station companies during the past year shows from the data furnished by 1,188 central station companies that no fewer than 75,000 electric street signs were in use in the United States, yielding an income of over $4,000,000 a year from power consumption.

Before noticing the more radical innovations in the art of incandescent lamp manufacture it is well to put on record the improvements which have come from the perfection of familiar processes, and have gradually reduced the selling price of the lamp of the carbon filament type to a point where practically ten lamps are sold for a dollar instead of one. The carbon filament lamp, when introduced, contained about thirty times as much platinum in the leading-in wires to which the carbon strip is attached as does the lamp of the present day. The exhausting of air from the lamp by mercury pumps in order to create a high vacuum now requires but a single minute, where half an hour was necessary ten years ago, and from four to five hours at the beginning of the art. As a matter of fact twenty-five years ago the mere cost of exhausting a lamp was greater than the whole cost of the lamp at the present time. All the glass blowing operations on the bulb have been changed from hand work with expensive skilled labor to machine work that a tyro can regulate, and the labor cost of the glass processes is barely 10 per cent of what it was in 1882. All the lamps sent out are tested by photometric process, but to-day that incidental work costs but one-tenth of what it did formerly. The first successful lamps were based upon carbon filaments made from paper and bamboo, but at a very early stage cellulose material was employed, and it has now come into universal use. Such lamps, of a standard 16-candlepower capacity, require but 50 watts of electrical power for their full efficiency, so that the current consumption has also

been cut in two. It is estimated that in the first quarter of a century 250,000,000 incandescent lamps of carbon filament type were produced, or at the average rate of 10,000,000 a year; but, as the figures already quoted indicate, the total number is now over 100,000,000 a year.

It is probable that for some time to come lamps of the carbon filament type will continue to be manufactured in large quantities, but even in these important improvements have recently been made, the object being to secure high candlepower with less consumption of current. The principal lamp of this modified character has what is known as the "metallized" carbon filament, which is rated at 2.5 watts per candlepower, as compared with the plain carbon filament type, whose standard consumption has been 3.10 watts per candlepower. The new filament is obtained by applying an additional process to the ordinary carbon filament, the treatment including heating in an electric furnace to a temperature of from 3,000° to 3,700° C., this firing being performed both before and after treatment. The additional processes result in the production of an exceedingly pure form of carbon, having greater density and considerably less specific resistance than the older filament, while the temperature coefficient is changed from negative to positive. For this latter reason the term "metallized" has been employed to describe the new filament, although it contains no metal. These lamps are now generally available in all the standard sizes and have immediately become popular.

A far more important and radical advance is that which has been made in the production of incandescent lamps with metallic filaments in place of carbon. Some of the very earliest work in the subdivision of electrical current for lighting purposes was done with filaments of a metallic character, such as platinum, but these were found at the time insufficient to serve as the basis of a commercial art, although hope in that direction was not entirely abandoned. Experiment has been maintained for many years, and the first success is due, as in so many other fields of chemical and metallurgical research, to the perseverance of German scientists. Several years ago, with the fundamental principle as a starting point, that the visible part of radiation from an incandescent lamp filament increases progressively with the temperature of the filament, elaborate laboratory experiments were begun in Germany to discover a metal that would withstand a much higher temperature than the carbon lamp filament can endure economically. The result of a long series of tests was to determine the selection of tantalum, which in a pure state was found to yield very satisfactory results.

The chemical properties of tantalum are very remarkable. When cold, the material strongly resists chemical agents; it is not attacked by boiling hydrochloric acid, nitric acid, or sulphuric acid, and it is also indifferent to alkaline solutions; it is attacked solely by hydrofluoric acid. Heated in the air, it assumes a yellow tint at about 400° C. like steel, and also like steel the tint changes to dark blue when the tantalum is exposed for some time to 500° C. Thin wires of it when ignited burn with low intensity and without any noticeable flame. It greedily absorbs hydrogen as well as nitrogen, even at a low red heat, forming with them combinations of a metallic appearance, but rather brittle. It combines with carbon very easily, forming several carbides which, as far as they are at present known, are all of metallic appearance, but very hard and brittle. When in the form of powder, still containing, as previously stated, oxide and hydrogen, the specific gravity is about 14; when purified by fusion and drawn into wire, it has a specific gravity of 16.8. It is somewhat darker than platinum and is about as hard as mild steel, but shows greater tensile strength. It is malleable, although the effect of hammering is relatively small, so that the operation must be long and severe to extend the metal into a sheet. It can be rolled as well as drawn into very fine wire. Its tensile strength as a wire is remarkably high and amounts to 133,000 pounds per square inch. The electrical resistance of the material at indoor temperature is 0.165 ohm for a length of 1 meter and a section of 1 square millimeter; the temperature coefficient is positive and has a value of 0.30 between 0° and 100° C. At the temperature assumed by the incandescent filament in the lamp under a load of 1.5 watts per candlepower, the resistance rises to 0.830 ohm for a length of 1 meter and a section of 1 square millimeter. The Siemens-Halske Company in Germany has taken out about 200 patents on the tantalum lamp, comprising about 1,000 claims. Experiments with many hundreds of the tantalum lamps gave a useful life of four hundred to six hundred hours, during which it consumed about 1.5 watts per candlepower. Useful life is defined as the time at the end of which the lamp has lost 20 per cent of its "light power." The candlepower increases during the first one hundred hours, whereby the specific power consumption decreases to about 1.3 watts per candle. The latter then increases, and at the end of the useful life the lamp consumes 1.8 to 2 watts per candle. The lamp, however, continues to burn for one thousand or one thousand five hundred hours. It is found to burn much better on direct than on alternating current, as the latter appears to disintegrate the filament rapidly; and in the United States it is now being used only on direct current circuits. The price to the retail purchaser of a 22-candlepower tantalum lamp, consuming 44 watts of electrical power, is 60 cents; and the New York Edison Company, which supplies new lamps free to its customers, makes a charge of 35 cents for this lamp. This practice may be taken as an index of the general practice

of the central station companies in introducing the new illuminant. The makers in Germany have produced and placed on the market a 2.2 watt lamp for pressures of 50, 55, 60, 65, 75, 100, and 110 volts, whose useful life is quoted as being from eight hundred to one thousand hours, with the total life often reaching one thousand five hundred or two thousand hours.

Another lamp of the metallic filament type is the osmium, which has been introduced to some extent in Europe but is not yet widely known in the United States. The crude material is very finely divided osmium—one of the rare metals—which is mixed with binding substances so as to form a thick, tough paste, which is forced under very high pressure through a die. A thread is thus obtained, which is formed into loops. The threads are then dried and heated in a vacuum in order to carbonize the binding material, and they are next subjected to the processes of formation. The threads, which at this stage consist of porous, rough osmium with a high content of carbon, are heated for a long time by means of electric current, being brought gradually through higher and higher temperatures to white heat in an atmosphere containing a great deal of steam and various quantities of reduced gases. In this manner the filament becomes pure porous osmium of a far greater density than the original rough thread. During the use of the lamp the osmium surface becomes gradually smoother and smoother, which accounts for the increase in the light given out by the lamp in the first few hours of use. The filament, which has an approximate length of 15 inches, is divided into three separate loops connected in series by means of two loops of platinum wire, the middle of each of which is fused, by means of a glass bead, to the top of the stem carrying the two leading-in wires. Each filament is anchored in order to prevent the loops from touching the dome of the bulb, and the anchor device consists of a small glass rod to the end of which is attached a turn of small wire or white refractory metal. The filament is anchored not at its extremity but somewhat above the turn of the loop. The lamps can be burned only in a vertical downward position. The consumption is 1.5 watts per candlepower, and the standard type is a 50-volt 25-candlepower lamp, guaranteed at that consumption of electrical power. The useful life of the lamp is given as about two thousand hours, but some have been burned five thousand hours. The osmium lamp is somewhat more fragile than the ordinary carbon filament lamp if exposed to hard knocks, but it seems able to withstand a great deal of vibration, as in train lighting, for which it has proved satisfactory in connection with storage battery equipments. Its low voltage has also made it desirable for mine safety lamp purposes.

Another lamp of this character is one in which the filament is made from a metal alloy of which the rare metal zirconium is a component. Lamps of this kind require only a small pressure, such as 2 or 4 volts, and hence, like the osmium, are available more particularly in connection with storage batteries. Tests on these lamps show that 2-candlepower lamps at 4 volts give a consumption of 0.92 watt per candlepower, whereas the ordinary carbon filament lamp of the same low candlepower consumes 3.8 watts. The lamp is expensive in first cost, but, as will be seen, the cost of operation is low, and a more recent lamp of this type is reported to have a consumption of 1.2 watts per candlepower with a life of five hundred hours, but needs careful handling and is commercial only on low voltages.

The latest development in metallic filaments for incandescent lamps relates to the work on tungsten, conducted principally abroad, although in the last three or four years a large amount of research and investigation has gone on in the United States also. The merit of the tungsten lamp consists in the fact that it consumes only between 1 and 1.25 watts of electrical power per candlepower, as compared with the 3.10 of the ordinary carbon filament type, 2.5 of metallized filament, and the 2 watts of the tantalum lamp. While tungsten is considered one of the rare elements, its compounds are already of considerable use. Sodium tungstate is employed in impregnating fibers to make them fireproof, and as a mordant in dyeing. Tungsten bronzes are employed largely as bronze powders and pigments. The chief employment of tungsten in recent years, however, has been for high-speed tool steels and for ordinary steel in armor plates and large guns. A few years ago very little was produced in this country, but the quantity of tungsten concentrates reported for the year 1905 was 803 tons. The tungsten concentrates valued formerly at $2 or $3 per unit are now worth at least $6 per unit, the unit meaning 1 per cent of a ton. It will be obvious, therefore, that tungsten is a rare element, although not in the same sense as osmium or platinum. Like most metals proposed for incandescent lamp filaments, tungsten has a lower electric resistivity than carbon, and for this reason the manufacture of high voltage tungsten lamps is a more difficult process than is the production of carbon lamps for the same voltages—say, the standard, 110. In the main, however, these difficulties in the manufacture of tungsten lamps have been successfully overcome, as the lamps are now on the market in both Europe and the United States.

The fundamental value of tungsten for lamp filaments lies essentially in its enormously high point of melting or volatilization. In this respect it perhaps resembles carbon and the nonmetallic elements. In the common use of the word "metal," pure tungsten is virtually unknown. It has not yet, for instance, been reduced to ingot form from which anything could be hammered, or cut, or drawn. Hence, so far as is known, a filament of wire such as is used in the tantalum lamp, for example, can not be paralleled or dupli-

cated from tungsten, so that the filaments now in use in tungsten lamps have to be obtained by what may be called roundabout methods, and when completed are like carbon filaments, aggregations of amorphous structures or of infinitesimal crystals. Three different processes are in use for making tungsten filaments.

The first process is based on the effort to coat a carbon filament with tungsten and results in the simultaneous dissolution of the carbon filament, and its replacement by finely divided tungsten, which is strengthened by a process akin to "flashing," or, in other words, the heating up of the filament in the vapor of a tungsten compound. The other two processes start with very finely divided tungsten, worked up into a paste, from which the filaments are formed. Further treatment is then given by firing. The earlier processes dealt with a paste made of what may be called precipitated tungsten. The later process is based on so-called colloidal metal, which presents the advantage of almost infinitely fine subdivisions. The result is of the same nature, whether the filament is prepared by the "substitution" process, the paste process, or the colloidal process—namely, an extremely fine thread 1 or 2 mils in diameter, of compactly aggregated pure or nearly pure tungsten. These filaments are dense and of smooth and uniform appearance, but thus far appear to be quite brittle, as might be anticipated from their structure. The elimination of this tenderness is one of the problems of the future for this new lamp. These lamps have an advantage over the tantalum in the fact that they can be burned equally well on both alternating and direct current; but like the tantalum, the tungsten lamp is best burned in a vertical downward position, although in this respect it more nearly resembles the osmium. The lamps that have been introduced commercially are rated at 25 candlepower, consuming 1 watt per candlepower and are given a life of not less than one thousand five hundred hours. A standard lamp introduced in Europe and already known in the United States consumes 40 watts and has three filament loops with a total length of filament of 17 inches.

The statistics of decorative or miniature lamps, etc., include also vacuum tubes, vacuum and vapor lamps, and X-ray bulbs, which are not enumerated separately. The vacuum tubes and lamps are used for lighting and for photographic purposes. The X-ray is now employed almost exclusively for surgical investigations, chiefly those by which the interior of the human body can be inspected, and broken bones, foreign substances, etc., be located. The vacuum tubes consist principally of those based upon the utilization of the vapor of mercury. This type has been upon the market since 1903 and has come into extensive use. The words "vacuum tube" are employed generically to distinguish the exhausted bulbs or lamps which contain no filaments, but which have in them gases other than air or such metals as mercury, which will when vaporized "carry the arc," so to speak, and will thus maintain illumination. In the leading lamp of this type the light giving element is a gaseous vapor of mercury inclosed in a hermetically sealed glass tube, varying in length from 17 to 45 inches, and about 1 inch in diameter. This tube is suspended from the ceiling and is mounted on a tilting arm, suspended from a pendant canopy which contains the regulating mechanism. When the current is turned on the mercury becomes vaporized, thus maintaining the circuit throughout the length of the tube, which becomes wholly luminous. The complete lamp outfit may be said to comprise the exhausted glass vacuum tube, the holder and reflector, and the auxiliaries.

The tubes intended to operate on direct current have a positive electrode of iron at one end and a negative electrode of metallic mercury in a bulbous cup at the other end. The tubes for alternating current lamps have two positive electrodes of iron at one end and a negative electrode of mercury at the other end. The alternating current enters the vacuum by the positive electrode and leaves the tube by the negative electrode. These alternating current lamps operate in reality as a converter, in application of the principle of negative electrode resistance, which will be referred to later. In all types of the tube the terminal connections to the sources of electrical supply reach the electrode through platinum wires. The lamps are set in operation by tilting them for an instant, either mechanically, by pulling a small chain attached to the upper end, or automatically, by means of a small magnetic attachment. This tipping of the higher end of the tube causes the mercury to flow from one end to the other in a small stream, which bridges the vacuum in the tube momentarily, thus closing the circuit through the tube, and the resulting arc of current vaporizes some of the mercury. The subsequent steady flow of electrical current in the vacuum, after the return of the lamp to the normal position at a slight angle, increases the vapor pressure and excites it to a high degree of luminous incandescence. The holder or fixture bracket for the tube consists of a lamp rod with clamps, from which the tube can be easily removed or inserted, and the suspension bar hung close to a light colored ceiling without reflectors, or else equipped with flat or curved reflectors of different styles. The standard flat reflectors, 6 inches wide, are used generally where the lamps are hung at some distance from the roof or ceiling. The faces are white enameled so as to increase the diffusion of light, while the reflector tops and holders are finished in a lustrous black. The auxiliary consists of two or three coils of resistance wire, an inductance coil, and a ballast bulb intended to correct abnormal voltage variations on the line, all being connected in series with the tube. This auxiliary mechanism is placed within a

small canopy, heat insulated from the ceiling by an asbestos shield, and fastened to the ceiling on a plate attachment having a claw foot into which the suspension bar is secured.

The standard type of lamp of 700 candlepower for direct current is 55 inches long, with a length of 45 inches of light-giving tube. It is operated at 3½ amperes and consumes 385 watts when installed single on 110 volt circuits, or 0.55 watt per candlepower.

The direct current lamp is made in two sizes—one 24 inches long, 17½ inches of tube, giving 260 candlepower; and the other 27½ inches over-all length, with 20¾ inches of tube, giving 300 candlepower.

The alternating current lamp of 425 candlepower is 34 inches long, with a 28-inch tube, and is designed to operate on all single phase circuits of a frequency of 60 cycles or more. It consumes 275 watts, or 0.64 watt per candlepower. These tubes appear to have a long life, ranging in many cases over ten thousand hours, although they become somewhat blackened with long service.

The absence of red rays in the mercury vapor lamp renders it undesirable or inapplicable for every purpose, but it is found particularly useful in industrial and other plants, and it may be noted that all the United States Government currency and internal revenue stamps are printed under its light in the Bureau of Engraving and Printing at Washington, where the nature of the presswork requires a high quality of widely diffused light. Another typical instance of its use is in the New York Times building, where no fewer than 42 of these tubes are employed, of which 26 are in the press and stereotyping rooms, lighting an area of 1,700 square feet. Mr. Peter Cooper-Hewitt, who is to be credited with the development of this lamp, has improved the color of the light by the addition of the vapors of lithium, potassium, and rubidium, which will, however, attack the tube if made of quartz. Other attempts in the direction of changing the color of the light involve the introduction of inert gases, such as neon, nitrogen, or argon. Means adopted, external to the lamp itself, to supply the deficiency of red rays have met with no marked success. In the meantime the lamp, during the past two or three years, has become so widely used as no longer to excite comment, and the prejudice or objection to the color has died out so far as any industrial work is concerned.

There are one or two other systems of mercury vapor lamps, including those in which incandescent lamps have been associated with the tube, so as to secure an agreeable blend of the two lights. A more distinctive variation, however, is found in the Moore system, which is based upon considerable lengths of tube, ranging as high as 200 feet all in one stretch, giving an unbroken band or cornice of light around the room or space thus illuminated. These long tubes are made on the premises of the customer by sealing hermetically together tubes that come in lengths of 8 feet 6 inches, a new portable gas fire having been worked out for this purpose. The lamp is of the alternating current type, the electrodes reversing their sign at each alternation, necessitating high voltage to be applied at the terminals in order that the intervals between the successive impulses will not be apparent to the eye, which would otherwise be disagreeably affected by the unsteadiness or fluctuations of the light. All the distinctly electrical apparatus is placed in a single steel case or box, from which the tubes extend for illuminating purposes. A low-potential alternating current circuit supplies the apparatus with electrical energy at 60 cycles, and the tube contains a nonmetallic gas or vapor under very small pressure. The terminal of the tube within the box contains at each end carbon internal electrodes. Within the box also is the step-up transformer, to the low-potential coil of which current is supplied, the high-potential terminals being attached directly to the tube electrodes. Hence the only wires extending from or into the box are the ordinary low-potential service wires. Some of these tubes are 150 to 200 feet in length with a diameter of 1¾ inches, operating at a brilliance of 4.2 candlepower per foot of tube. The efficiency varies with the length of the tube, and an actual total candlepower for one instance is claimed of 2,200 with a total consumption of 3,300 watts. The tube, in addition to being operated in continuous lengths—as, for example, around the four sides of a room or of a long passageway—can be bent back and forth into frames for photographic purposes or can be made to follow the irregular outline of a building or portico, and can even be twisted so as to form letters and spell words. In this last form it lends itself admirably to advertising purposes. The color of the light is excellent, and for the illumination of large areas such tubes appear to have a promising future, although apparently they can not be used economically in small units or short lengths. An effective illustration of their employment is furnished in one of the largest department stores in New York city, where two tubes of 154 feet each, attached to the ceiling of a basement floor, have displaced nine arc lamps and give effective and agreeable illumination over goods of a very varied nature.

In passing, a most ingenious and important utilization of the mercury bulb or vacuum tube must be noticed in respect to its use as a converter, transforming alternating to direct current in places where only the former is available and only the latter is desired. The possibility of conversion of alternating current into direct current in this manner depends upon the laws which underlie the familiar starting characteristics of the mercury vapor lamps. In the lamp the reluctance to start was in some respects an obstacle,

while in the converter the whole function depends upon this resistance; and the invention was an extremely ingenious means of rendering useful what was otherwise a troublesome characteristic. Various types of this apparatus are now largely used, principally for the charging of storage batteries from an alternating current circuit, and but for the existence of this device the batteries which can be charged only with direct current would require step-down transformers and rotary converters. In other words, they would need costly miniature reproductions of the substations familiar in electric railway and central station lighting.

The whole transformation of current for a set of automobile storage batteries takes place in a vacuum glass bulb resembling a very large pear, in the standard outfit about 9 inches in diameter. This glass globe has two or more positive electrodes of iron at the top, by which the alternating current enters the vacuum. At the bottom of the globe is a small pool of mercury constituting the negative electrode through which the current takes a continuous or direct outward flow to the batteries or other devices. Through the action of the negative electrode resistance, the positive electrodes pass current only into the bulb, and oppose any flow of the current from it. The current can therefore flow in one direction only—through the pool of mercury at the base of it—so that the impulses, waves, or fluctuations of alternating current are diverted from the alternating circuit and leave the vacuum in the form of the desired positive or direct current. The starting resistance of the negative mercury electrode is overcome by tilting the converter bulb until the mercury connects with the mercury of a small supplementary electrode, and current passes between the two. This tilting is accomplished automatically when the alternating current and direct current switch and the converter switches on the panel board in front of the globe are thrown in, and is repeated automatically upon the resumption of the flow of line current after interruption from any cause, so that an excellent protection is afforded against reversal of current. The efficiency of such apparatus is said to be not less than 80 per cent in supplying current at 115 volts to a set of from 20 to 44 cells of storage battery, and the whole converter equipment occupies a space of but 15 by 22 by 26 inches. Such an equipment has a minimum operating current of about 6 amperes and a maximum capacity of 30 amperes in continuous running, giving direct current voltage of from 50 to 115 volts. It may be noted that a certain amount of voltage is absorbed in the converter bulb itself, namely, 15 volts, which is practically independent of the volume of current flowing and which appears as heat and a slight quantity of light within the bulb and which is dissipated into the air through the glass.

A type of lamp that belongs in neither the arc nor the incandescent field, but which is also included in the statistical group of decorative and miniature lamps, etc., in Table 12, is the Nernst, which has come into widespread use since the date of the last report, and is now in operation in connection with hundreds of central stations and isolated plants in the United States. This lamp, which owes its origin to a German scientist, has as its light-giving member a glower, which although not brought to incandescence in a vacuum, as is the filament in the ordinary incandescent lamp, at the same time does not burn away as does the carbon in the various forms of arc lamp. The glower is made by passing through a die a dough composed of the oxides of rare earths, mixed together with a suitable binding material. A porcelain-like thread or string is thus obtained which is cut, after drying, into short, convenient lengths and is then baked. Platinum terminals are attached to these glowers, which are then ready for insertion in the lamp. The terminal connections between the glowers and the leading-in wires, as made by Doctor Nernst, consist of a few turns of platinum wire around the end of each glower, the convolutions being finally pasted with cement. A later form of successful terminal is that in which little beads of platinum are embedded in the glower ends, to which the leading-in wires are subsequently attached in such a manner that any shrinkage of the glower material results in a firmer contact with the platinum. The peculiar feature of glowers is that when cold they are insulators, but they become conductors when hot, so that they must be heated before they will pass electrical energy sufficiently well to maintain themselves at a light-emitting temperature. Moreover, as the glower is an oxide, incapable of further oxidization, it is operative in the open air or within loosely closed globes, and being, moreover, capable of withstanding a much higher temperature than is the filament of the ordinary incandescent lamp it admits of great economy in operation, while furnishing a light of remarkably superior white quality and color. The glower in a standard 220-volt Nernst lamp is 1 inch long by $\frac{1}{32}$ inch in diameter. Hence it is in sharp contrast to the ordinary carbon filament as to length and thickness. It is obvious that as the glower is a nonconductor when cold it requires some form of heater to bring it up to a conducting temperature, so that current can flow through it and cause incandescence. The glower becomes a good conductor at about 600° to 700° C. Various forms of heaters have been made to work automatically, as the earlier forms of lamps in which the heating was done by hand were far too slow and cumbrous for commercial practice. The heaters in common use consist of thin porcelain supports mounted with fine platinum wire, which in turn is held in place and protected from the intense heat of the glower by a refractory paste.

Associated with the heater is a cut-out, which disconnects the heater from the circuits as soon as the glower lights up, which takes several seconds. The

cut-out comprises a small coil, an armature, and contact, the coil being heat proof and embedded in cement, while the contact is nonoxidizable, being of silver. The heater circuit is normally kept closed by the force of gravity, as the lamps are operated in the downward position, although a successful form of universal cut-out is available which will operate with the lamp in any position. The mode of operation of the lamp is therefore the admission of current to the heater, making it white hot, whereupon its proximity to the glower causes the latter to become a conductor through which the current then passes. When the current through the glower has reached the predetermined proper amount, the cut-out coil becomes energized by the glower current passing through it, and the arm of the cut-out which had hitherto closed the heater circuit is attracted and opens the heater circuit, so that only the glower is left in operation.

Another part of the lamp is its ballast, or steadying resistance, of fine iron wire. The conductivity of the glower increases with the temperature, so that if used directly on a constant potential circuit this temperature would continue to rise, and very soon the increasing amount of current flowing would destroy the glower. Hence the steadying of the current is accomplished by this ballast of iron wire, which possesses the property of increasing its resistance with great rapidity on reaching the critical temperature, and operates to prevent short circuiting, or "flashing out." Thus with a 10 per cent rise in current, the increase of resistance in the ballast is 150 per cent, so that the glower is thus protected through a wide range of supply voltages. This iron wire is guarded from the air to prevent its oxidation and the rapid change of temperature, and is therefore mounted in a little glass bulb filled with hydrogen, which is an inert gas and conducts the heat from the ballast to the walls of the bulb better than other gases. These diminutive working parts are all mounted in the lamp body in a suitable manner. The glower and its heater of course project into the surrounding glass globe, while the other parts are inclosed in a canopy from which the globe depends. The main features are alike in all the lamps, and various sizes, or degrees of illumination, are obtained by assembling one or more standard glowers with their auxiliaries within the canopy and globe. Hence the smaller lamps are burned with but a single glower, while in the larger type as many as six glowers are employed. The perishable parts, such as glowers, heaters, and ballasts, are easily renewed, being mounted in removable pieces called the "holder," which may be pushed into place or taken out like an incandescent lamp with regard to its socket. The lamps are burned usually on alternating current at a frequency of 60 cycles and preferably at 220 volts, those in use in this country having a range of use on any frequency of from 25 to 133 cycles. The lamps are made for both 110 and 220 volts, and one glower lamp at 110 volts has a consumption of 44 watts of electrical power. The 6-glower lamp at 110 volts has a consumption of 556 watts and at 200 volts a consumption of 528 watts.

A development of interest during the past year in connection with the Nernst lamp has been the making of a series lamp of moderate candlepower for street illumination, thus allowing the lamp to be used in places where a fairly large number of small units is required. The outfit consists of a single glower lamp connected with a series transformer, the primary coil of which is adapted for a circuit carrying 6.6 or 7.5 amperes of constant alternating current. Hence the lamp may be used on any of the constant current series systems, and the ordinary 50-light "tub" transformer will energize about 200 lamps of this new type. The glower and heater in this particular form of lamp are mounted in a vertical position on a porcelain base, and the heater is made in the form of a helix around the glower. Another exemplification of the use of the lamp is afforded by the huge new terminal of the Pennsylvania Railroad in New York city, for which this type of lamp has been adopted, and for which no fewer than 20,000 glower units will be required.

Lighting fixtures.—Table 13 presents statistics of electric light fixtures for 1900 and 1905.

TABLE 13.—*Electric light fixtures—value: 1905 and 1900.*

STATE.	Total value.	Fixtures (value).	Lamp sockets, receptacles, bases, etc. (value).
United States, 1905	$5,305,466	$3,294,606	$2,010,860
1900	4,344,599	3,750,670	593,929
States, 1905:			
California	447,109	447,109	.....

[3] Includes states as follows: Illinois, Massachusetts, New York, Ohio, Pennsylvania, Rhode Island, and Texas.

A considerable increase is shown in the value of electric light fixtures of all kinds reported in 1905, the amount being $5,305,466, as compared with $4,344,599 in the year 1900. The increase is accounted for to a great extent by the larger manufacture of sockets and bases incidental to incandescent lamps, for which an increase of 238.6 per cent was shown for the period, but the bulk of the amount is, as before, represented by the fixtures themselves. It will have been gathered from the preceding data as to the development of electric lamps of new forms and characteristics, that there has been a considerable development also in the fixtures to hold these lamps, none of these newer fixtures being known or included in the statistics at the time

of the previous census. The Moore vacuum tube, the Hewitt and Steinmetz mercury vapor lamps, and the Nernst lamps all require special fixtures of their own for their most efficient use, and even some of the new forms of incandescent lamps have had special fixtures carefully designed for them, in order to secure the best results in diffusion and distribution of light. For example, the new metallic filament lamps are associated with fixtures and special types of holophane reflectors, which are harmonized in their relationship to the lamp and to each other, with a great gain in efficiency of illumination and of general artistic effect. As a matter of fact, the whole art of fixture designing and construction has undergone a very marked change and improvement during the last few years, on account of the coming into existence of the distinctively new branch of illuminating engineering, which is already so well recognized that it is represented by a national society with upward of 500 members. It has been estimated that the yearly expenditure for lighting in the United States is well above $200,000,000, of which at least $20,000,000 is wasted on account of the use of improper fixtures, shades, reflectors, etc., and the aim of these specialists in illumination is to work in close relationship with the architect, the decorator, and the designer of gas and electric fixtures.

The modern art of illumination may be said to have broken away entirely from the standard and stereotyped bracket and chandelier associated with the use of gas. The adoption of electricity, with its greater flexibility of application, has permitted the use of many methods quite impossible with other illuminants. It is obvious, even to the casual observer, that a great deal of modern lighting within doors is done without fixtures and is in the nature of overhead or cove lighting, where the lamps are concealed within a hollow cornice; or else the lamps shed their light through a transparent ceiling so that there is a general diffusion without any small individual illuminant being presented to distract or annoy the eye and with a general absence of glare. This method of diffusing light has become very popular for large spaces. At the same time the electrical fixtures must always have a conspicuous place in the art of illumination, and these are made in greater quantity than ever, while increasing attention is paid to their finish and artistic design.

It is said that the first incandescent electric light fixture was made as early as 1842 by Mr. William Pearce, of Boston, Mass., for Mr. George Peabody, the banker and philanthropist, who was assisting in his electrical experiments an unfortunate young inventor named Starr, who anticipated much of the practical development of electrical illumination that did not come until nearly forty years later. It is said that this pioneer fixture had no fewer than 26 little lamps set in sockets, fashioned like ears of corn, symbolizing the then 26 states of the Union. The bulbs were of molded glass to imitate kernels, and the socket had leaves of sheet brass hammered into the likeness of cornshucks. Thus early it will be seen that the artistic value and adaptability of incandescent lamps was appreciated. The range of electric light fixtures is to-day so infinite that it is impossible to enumerate them all or to do more than characterize them. A good example is afforded by any new edifice, and for such purpose the new Federal building in Chicago will serve, the equipment there being of unusual size, providing for some 15,000 lamps. The first installation contained over 10,000 lamps of 16 candlepower, while the later development of studies with regard to the fixtures and the use of cove and concealed lighting has rendered possible the employment of lamps of 4, 8, and 10 candlepower, so that the present installation is the equivalent of 15,000 lamps of 8 candlepower. In order to permit the use of these lamps no fewer than 2,970 outlets in the building were furnished with electrical fixtures, which have been installed at an expense of about $50,000. In the main rotunda 900 lamps of various powers are employed, many of them in fixtures carrying a holophane globe, placed around galleries and corridors, and with 16-globe electroliers, which are hung at the first floor level, and at the face of the rotunda floor level 100 feet higher. The brackets or electrical fixtures for this purpose cost $400 each, and are constructed of cast brass, weighing 750 pounds each. The globes, 30 inches in diameter, are of leaded white ground glass illuminated with 12 ruby-colored 8-candlepower lamps inside and with a row of eighteen 8-candlepower white frosted lamps around the equator. The main vestibules, which are finished in granite, have 12 large fixtures of architectural design and generous proportions of the bracket type, each carrying a sandblasted globe which contains six 16-candlepower lamps. The stairways are further illuminated with massive newel post stands, while in the corridors and rooms are stalactite fixtures and a variety of other wall brackets and ceiling clusters harmonizing with the general treatment of the building.

Special treatment of this character will, in fact, be found in every large new building now erected, and in some instances the purpose of the building calls for novel fixtures, as, for example, those installed in the main dining room of a large new hotel in New York, where the fountains that play during mealtime are in the nature of electric fixtures with the lamps shining up from the base through the water.

Telephone apparatus.—Table 14 shows the number and value of telephones and telephone apparatus and supplies for 1905.

The total value of telephonic apparatus manufactured, as reported at the census of 1905, had a value of $15,863,698, as compared with $10,512,412 for the census of 1900. These figures do not reveal all the facts, for during the period covered no greater activity was shown in any department of electrical application than in telephony. A very large proportion of other electrical apparatus, including dynamos, motors, motor-generator sets, insulated wires and cables, conduits, etc., were required for the equipment of telephone exchanges and in connecting the stations of individual telephone subscribers, and only an analysis of the product for these other fields, and an apportionment to the various branches of electricity, would bring out the high relative importance of telephonic development. As in the earlier figures of telephone manufacture, the value of products roughly divided itself in halves between the receiving and transmitting instruments, and the switchboards.

The value returned for the 4,283 central switchboards was $5,154,447, to which should be added the 3,917 private exchange boards of a value of $564,795, making a total of $5,719,242. To this should be added a large proportion of the value of $2,071,895 reported for telephonic parts and supplies. The subscribers' apparatus used in connection with these exchange boards and smaller equipments was reported as having a value of $8,003,735, of which $6,483,418 was represented by complete sets of transmitters and receivers. It will be noticed that individual transmitters and receivers, manufactured but not assembled into complete sets, very nearly balanced each other, as might have been expected, there being few uses for a telephone receiver when not associated with a transmitter, and vice versa. It will be observed also that the equipment within the central station exchange was broadly equivalent in value to that employed in the exterior equipment at the subscribers' stations, which according to this table would show a gross increase of about 1,700,000 subscribers during the year 1905. This sweeping assumption would not, however, be justified, for the reason that a great deal of apparatus is destroyed each year or becomes obsolete, so that the new simply replaces the old in a great many instances. No large fire occurred in any community—as at Baltimore or San Francisco—in which telephonic apparatus was destroyed in considerable quantities at the subscribers' stations; but even this diminution of apparatus already in use is perhaps not equal to that which is caused by the abolition of the older magneto-calling method and its substitution by the central energy system; it being necessary in the former case to signal the exchange by the manipulation of a little crank on the telephone set, while in the central energy or common battery system all that is necessary is to remove the receiver from the hook on the transmitter stand.

All the telephone exchange service of the country is furnished by the Bell system and by that which bears the general name of "Independent." The exchanges connected with the network of the American Telephone and Telegraph Company during 1905 reported an increase in the period of 441,734 stations. If it is to be allowed that the new connections to the independent systems proportionately equal this, it will follow that new equipment was called for by these subscribers to the amount of about 800,000 sets, which would indicate that about half the new apparatus manufactured goes to replace that which has been worn out, destroyed, or become obsolete. A certain amount, however, of

KEYBOARD CABLES FOR TELEPHONE EXCHANGE (SKELETON OF SWITCHBOARD SECTION IN THE REAR).

the telephonic apparatus made in the United States is exported; but the statistics of the manufactured exports do not give these figures in detail. A certain number of stations also are fitted up in connection with interior systems, but these in the aggregate are insignificant as compared with the central exchanges, for, while no fewer than 4,560 interior systems were returned, their value was only $68,826, from which it is evident that the number of stations connected—as, for example, on the different floors of a factory—would number but a few thousand at the most. It has been claimed that in recent years the number of independent telephone stations has increased more rapidly than the number of the Bell stations; but there are no exact data on the subject and the last figures available, namely, those of the Census report for 1902, gave a total of 1,317,178 Bell stations and 998,119 independent stations. There has been an enormous development of telephony in the great cities during the past five years, but at the same time one of the great features of telephonic increase has been the utilization of the telephone in rural districts, so that to-day no agricultural section of the country is without its village exchange and its farmers' lines.

The vital importance of the telephone system to the business and social life of the twentieth century may be shown by the fact that in 1905 the Bell system alone reported 4,532 exchanges in operation, 6,043,518 miles of wire in exchange and toll service, and 74,718 employees, with total exchange connections for the year of 4,360,996,000, or an average of nearly 14,000,000 per day. Even if the number of connections through the independent exchanges and networks should not equal this, it will be readily seen that an enormous amount of traffic in the nature of business, social, and family intercourse was transacted with the aid of the telephone, and indeed it would be impossible to imagine the conduct of American life upon its present basis without the telephone.

Illinois is the great center of the telephonic manufacturing industry in the United States, both as to number of factories and as to output. As shown in Table 14, this state accounts for more than half of the total value of product. It reports, for example, 588,750 complete sets of instruments, at a value of $3,942,343; 2,199 central switchboards, valued at $3,144,595; 1,153 private exchange boards, at a value of $179,031; and telephone parts and supplies, to the value of $793,026. The product in New York state was also quite large, although far below the aggregate in Illinois; the value reported for 104,180 complete sets of instruments being $982,834, and $1,695,709 for 776 central switchboards. It also had the largest proportion of the private exchange boards, numbering 2,194 and valued at $331,042. Both in Indiana and Ohio there was a fairly large production of apparatus, Indiana reporting 34,370 complete sets of instruments, valued at $334,170, and 328 central switchboards, valued at $105,387. The product in Ohio was about the same in quantity and amount, namely, 39,362 complete sets of instruments, valued at $382,275, and 203 central switchboards, valued at $122,500. Michigan and Massachusetts came next to Illinois in the manufacture of miscellaneous telephone parts and supplies, the output in Massachusetts being $210,967, while that of Michigan can not be shown separately. The product in the factories devoted to telephone parts and supplies is somewhat analogous to that in the bicycle and automobile field, these smaller factories chiefly making pieces which afterwards would be assembled into completed apparatus in the larger factories.

The telephone switchboards enumerated in this report are of two main classes—manual and automatic—which subdivide themselves into a great many varieties. The manual switchboard is that in which the connections between the subscribers are made at the central exchange by operators, who connect the lines of the different subscribers at the board by means of plugs joined by flexible conductors, all such connections being made in accordance with requests received over the line from the calling subscribers. These manual boards constitute a very large proportion of the boards included in the present statistics. There were in 1902 no fewer than 10,842 manual boards in use, and while no detailed figures are given, it is the fact that nearly all of the central switchboards and the private exchange boards made in the census year were also of the manual variety. This condition is likely from all appearances to continue for many years, although the automatic method has of late exhibited a rapid increase. During the past year fewer of the manual boards constructed were of the magneto type—in which each subscriber's substation has a small battery to energize its transmitter, and a tiny magneto-generator in the bell box, by revolving the handle of which the subscriber signals the central exchange. For all large boards of the manual type, as well as for a growing number of the smaller ones, the common battery system is in increasing favor, and in 1905 no new large exchange equipment in the United States can be named which was not of the latter type. In the common battery system, aside from the concentration of the source of all the electrical energy for the system at the central office there is another general feature which distinguishes it sharply from the older magneto-system. The signals on magneto-switchboards are of the electro-magnetic drop character, which operates in such a manner that when the current comes in from the subscriber's line, the drop or shutter corresponding to his line and carrying a number is dropped or otherwise moved, thus exposing the figures of the drop to the operator, who thereupon ascertains the wishes of the subscriber and connects him with the required circuit. The visual drop has long been con-

sidered inadequate to the needs of modern telephony, because the operator often fails to notice the falling shutter, and also because the shutter mechanism requires relatively so much space. In all the new large boards associated with the common battery practice the lamp signals are used, consisting of a very small incandescent lamp which flashes into visibility the moment the subscriber removes his receiver from the instrument at his office. When several thousand subscribers have to be represented and interconnected in the limited space of a multiple switchboard, the advantages of such signals are apparent, as they are extremely compact and hence economize space; having no working parts, they can be placed in any position vertically, horizontally, or at any angle; moreover, they are automatic in action, so that the signal disappears immediately when the energizing current is cut off. They also give a much more positive and attention compelling signal than any other form of indicator that has yet been tried in telephone practice. To quote the language of Mr. Herbert Laws Webb:

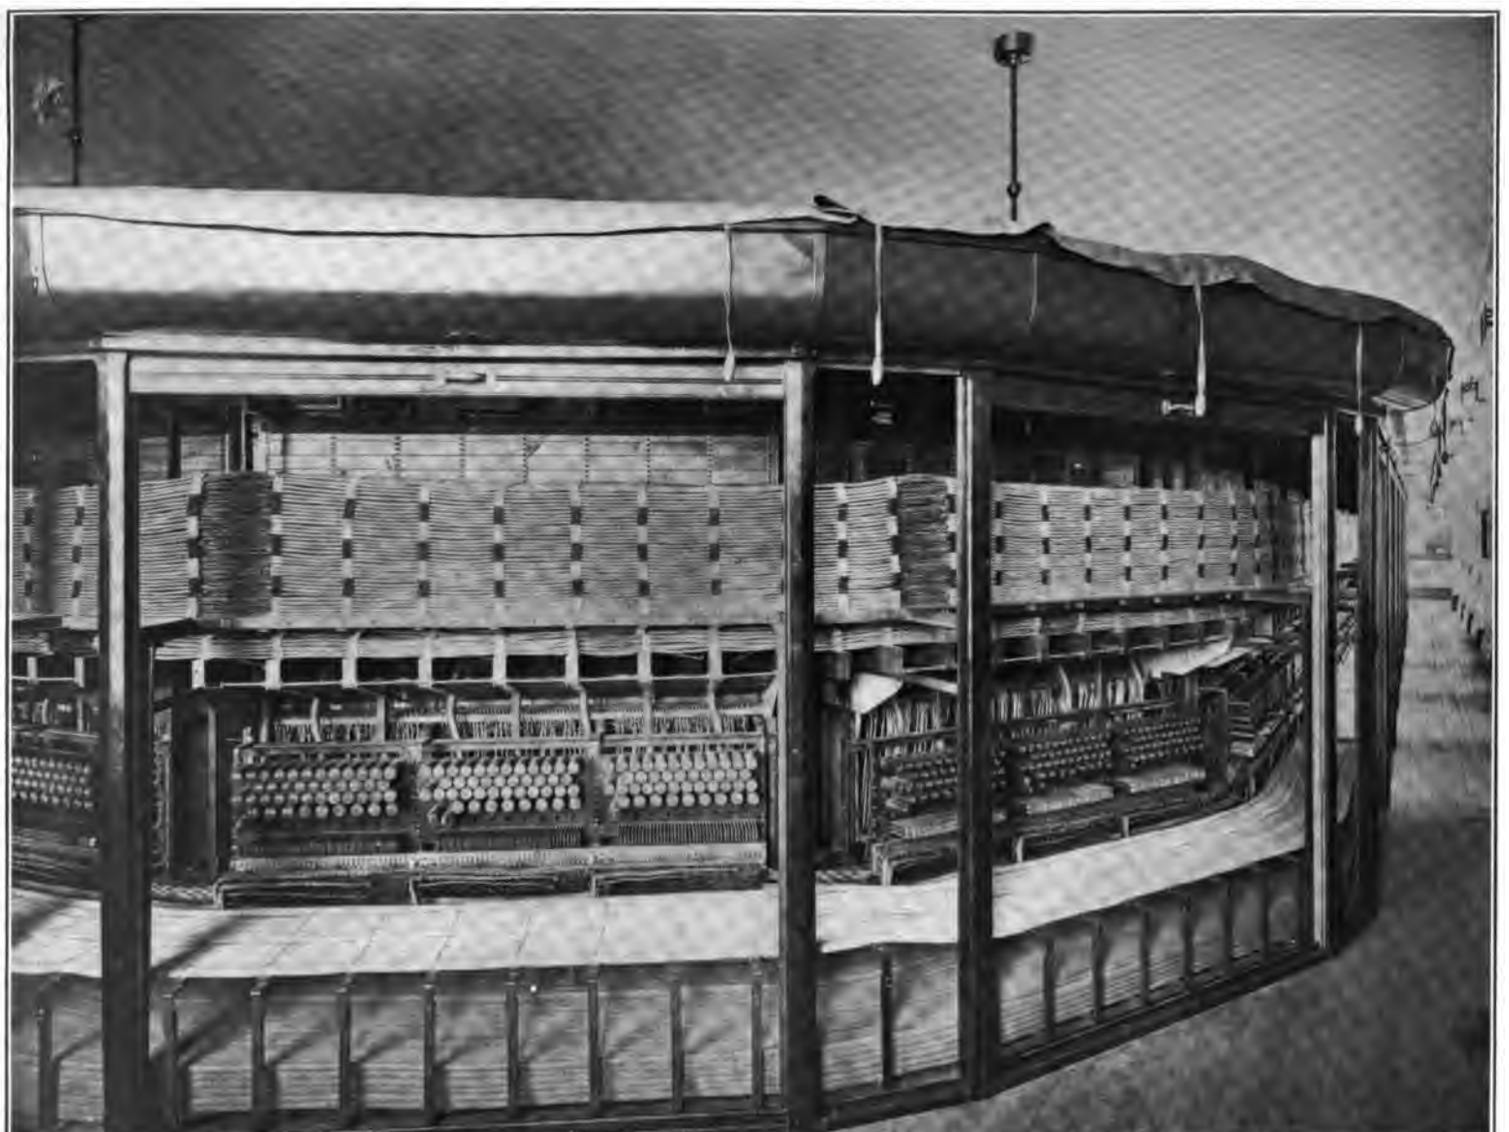
These various qualities enable several radical improvements to be made. The signals are placed immediately adjacent to the jacks or cords they control, which, in large switchboards, is impossible with electro-magnetic indicators; the line lamp is immediately above or below its corresponding answering jack and the supervisory lamps are in line with the connecting cords and close to them. With this arrangement the operator loses no time and has to exert no brain power in tracing the relation between the signal and its corresponding jack or cord. The difference in effect between the modern arrangement of directly associating the signals with their corresponding jacks and cords and the old arrangement of placing the signals in a separate part of the board from that occupied by the jacks and cords is something akin to the difference between a telegram in plain language and one in code. In the one case the meaning of the signal flashes instantly to the brain of the operator, and in the other case a certain effort, and a certain interval of time, are required for translating the meaning of the signal. The automatic working of lamp signals is of much wider range than that of electro-magnetic signals. We had self-effacing, or automatically restored indicators before lamp signals were introduced. But the self-restoring indicator had but two positions—only two words in its vocabulary, so to speak. The lamp signal has several; it may be alight or out, corresponding to the down and up positions of the indicator, but it may also flash, and it may be made to flash at different rates of speed, easily recognizable. Therefore, apart altogether from the fact that it is much more easy to apply to lamps distinctive marks indicating different classes of service than it is to apply such marks to indicators, the lamp signal is able to convey a greater number of meanings as a working signal than an indicator. Finally, the more assertive and positive signal given by a lamp as compared with an indicator is due to a simple physical fact—the great sensitiveness of the eye to light. The glowing of a lamp signal instantly attracts attention, no matter at what angle the lamp may be relative to the eye, and in many cases the lamp is seen instantaneously where a fallen drop would be unnoticed for several seconds. The lamp is seen out of the corner of the eye, so to speak, whereas an indicator must be more directly in the range of vision.

Mention has also been made of the fact that in the telephone switchboard of the modern common battery type the distributed battery, so to speak, that was formerly located in individual cells at every subscriber's station is now all centralized at headquarters, where it is far more available for inspection, renewal, maintenance, and continuous operation. The primary batteries that were formerly in use, scattered widely over a large territory, were subject to all kinds of accidents and interruptions from freezing, spilling of acids, corrosion, breakage of jars, etc.; whereas to-day the idle capital represented alike by the local battery and the magneto-generator with its incidental expenses, is done away with, and a large source of electrical energy is substituted, which stands ready at the central office to be drawn upon freely at any instant by any subscriber.

The work of the common battery office is performed with the aid of the storage battery, and the majority of such installations are operated at a potential of 24 volts, requiring a minimum battery of 12 cells. In most instances a duplicate of adequate capacity is installed and is associated with more than one method of generating, so that the services may be rendered free from all danger or possibility of interruption. It is stated that owing to the lessening of labor the operator, by these modern methods of signaling in common battery systems, can handle with success an average of about twice as many subscribers as with the old system. Another feature of this work has been the division of an exchange into virtually two sections to facilitate the transfer of communication at junctions from one circuit to another, the existence of supervisory lamps on the board enabling the incoming checking operators to signal back automatically to the answering operators whether the lines wanted are engaged or disengaged or out of order—the aim of this being to lessen the amount of trouble due to "line busy" or "engaged" difficulties that were the bugbear of all exchanges and the annoyance of all subscribers.

There is necessarily a great deal of complexity still about the modern common battery switchboard, but some of the gains resulting from its use are indicated in the striking statement that in a large exchange a room which formerly contained a magneto-switchboard equipment for 5,200 subscribers' lines, now contains a switchboard equipment of modern apparatus with lamp signals, which has a capacity of 9,600 lines. Moreover, the gain in time, due to the shortening up of the period necessary for connecting and disconnecting subscribers, adds greatly to the traffic-carrying capacity of equal plants under the two systems.

The other general class of switchboards included in this report is the automatic, in which all manual operations, whether of the magneto-exchange or the common battery system, are dispensed with, and all the operations of connecting and disconnecting are performed by automatic mechanisms at the central station set into motion by the subscriber himself. The subscriber's station consists of the usual telephone transmitter, receiver, battery, bells, induction coil, etc., with the addition of a call dial placed just below the



TELEPHONE SWITCHBOARD, SHOWING REAR VIEW OF SUBSCRIBERS' SECTIONS, WITH MULTIPLE CABLES, ANSWERING JACK CABLES, CORD CIRCUIT CABLES, AND RELAYS.

transmitter, on the periphery of which are ten numbered finger holes, carrying the numerals 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0. When the subscriber wishes to call a number, he takes the receiver down and moves the dial around successively step by step to the separate numerals constituting the number, when having completed the number he presses a button beneath the dial and rings at once the bell of the other subscriber called. If the line required is free, the connection is completed. If the line required happens to be busy, a buzzing sound in the receiver of the calling subscriber informs him that such is the case, whereupon he waits until the other line is clear. This step-by-step mechanism is simple and ingenious and works satisfactorily. For exchange purposes of the automatic system two classes of switches are employed. One set is known as the "selectors," of which there is one for each telephone connected with the central exchange; and the other is spoken of as "connectors," of which there are ten for every one hundred selectors, and which are in groups, each capable of connecting a hundred telephones. The selector connects its calling telephone with the connector in the proper group, which in turn connects with the required telephone in the group to which the connector belongs. This is employed in the case of exchanges of 1,000-line capacity or less. In larger exchanges a second auxiliary selector is employed, in the nature of an intermediate switch, which divides the work of selection with the first selector and therefore facilitates the work. These automatic switches at the exchange are mounted on steel shelves, 25 to the shelf, each board carrying four shelves of the first selectors and one shelf of the connector switches. This typical arrangement for central exchanges of 1,000 lines is modified in larger exchanges up to say 10,000 lines, where the board is made up of six shelves, four carrying the first selectors, one carrying second selectors, and one carrying the connector switches. The floor space occupied by such a condensed switchboard is 11 feet 6 inches by 12 inches in depth, and these boards or exchanges can be readily increased by simply adding new sections with the desired number of switches mounted thereon, without the disturbance of the board or the exchange already at work.

The system of trunking cables is similar to that in manual practice, and the selection of the trunk is automatically accomplished by means of the "wiping fingers" on the shaft of the selector switches, which pass over all the busy contacts and stop at the first idle point. The electrical equipment in the operation of the system follows generally the lines of the standard manual exchange, and consists of a 52-volt storage battery for furnishing current; and there are, as usual, cross-connecting boards or distributing racks, equipped with heat coils and carbon lightning arresters; a ringing machine, with "busy back" and "howler" attachments; a "telltale" board for the location of trouble; and the usual accessories of a small power plant.

The telephone switchboard is an exception to many other forms of construction, in that the cost per unit increases at a greater ratio than that of the mere physical enlargement of the board and of the system. The cost of a switchboard, in fact, ranges from $500 to $1,000 per square foot, varying according to the number of wires accommodated, while the life of the board is comparatively short. The system in New York city, for example, has practically been rebuilt three times in sixteen years, owing to the radical improvements made in switchboard systems and in the trunking cables, each time involving the abandonment of the then existing plant. Some of these exchanges have, in fact, been rebuilt three times in a little over ten years, showing an actual depreciation of 25 per cent per annum, although the old plant was not physically unserviceable. In a small switchboard with sections or places for two operators, there would be two sets of circuit branches and sockets for each telephone line, so arranged that the operator can make connection by plugging into them. In a large switchboard, however, with places for 50 operators there must be 50 sets of such connections for each telephone line—the number of this class of connections multiplying twenty-five times for each telephone, in order to enable each operator to reach all the subscribers who are connected into that central switchboard. The difference in cost of manufacture is immediately brought out by noting the material thus entering into the composition of a small switchboard of 600 telephones and one for 10,000 telephones, the individual items and details in each being alike and of the same cost. In the smaller switchboard there are only 43,000 soldered connections for the circuits, or about 72 to each telephone. In the larger switchboards, however, there are no fewer than 2,500,000 soldered connections, or 250 to each telephone. In the smaller board there is the quantity of 220 miles of wire circuit, or about one-third of a mile to each telephone. This in itself is very often as much wire inside the exchange for the subscriber as there is outside connecting his station with the exchange. In the larger switchboard, however, there are no less than 10,000 miles of wire, or at least 1 mile to each telephone. The other details follow in similar proportion, so that the whole expense per telephone is vastly greater in the larger boards, no matter what refinements or economies are introduced in the process of manufacture. Hence, as an actual fact, the cost of the largest boards will sometimes reach as much as $1,200 per foot of length, while one-third of the gross revenue of a telephone company is necessary to maintain such a board and the plant in good order without any reference to the cost of operation or of extensions.

As the statistics show, no fewer than 3,917 private

exchange boards were built during 1905. No such boards were enumerated separately at the census of 1900, although a number of them were in use, and it is probable that boards of this type were included in the class of "interior systems" at that census, as the distinction between these two classes of boards had not been clearly defined at that time. On June 1, 1905, there were as many as 6,637 private branch exchanges in Manhattan and the Bronx boroughs of New York city, with 17,704 central office lines furnishing service for 67,176 stations. The installations of this character vary from those with one or two lines or stations up to such large systems as that in a leading hotel with 1,200 telephones, or in a large dry goods store with 2,000. These private exchange boards are manufactured for many special uses and the advantages of their employment have been so great that the number of operators employed on the private exchange boards in New York city alone is more than twice the number of the operators in the central exchanges there. This concentration of lines from the individual telephones in business establishments to a single desk, where the desired interior and exterior connections can be made, has in reality done much to limit the size of the central switchboards themselves, as it is obvious that if every circuit were brought out to a central exchange, the boards would be of even more unwieldy proportions than they are now, while the outlook for the future would involve problems in switchboard construction with which no known resources of the art could grapple.

Including the separate transmitters and receivers, it would appear that a total of about 1,700,000 complete sets of telephonic substation instruments—that is, each set comprising a receiver and a transmitter—were manufactured in 1905, giving an average value of about $4.75 for each set, the total value being in excess of $8,000,000. The transmitters and receivers are of a great many different styles of construction, but all of them are essentially of the same nature in the two classes of apparatus, the differences being mainly such as might be expected where a number of manufacturers are endeavoring to give individuality to their products. All the transmitters now manufactured in the United States are of the microphone type, including the single contact, the multiple contact electrode, and the granular carbon varieties.

The prevailing theory as to the action in the transmitter is that as the pressure between the carbon electrodes or particles increases, the area of the contact increases so that it becomes denser, and is a better conductor. In the single-contact transmitters the resistance of the circuit is varied between two points forming a single contact. In the multiple electrode transmitter a number of pieces of carbon points, blocks, or balls are brought into contact. Several such transmitters were at one time in use, particularly for the purpose of long-distance work where a heavier volume of current was deemed necessary. However, few, if any, of these are now made, the prevalent and predominant type being that of the granular carbon. In this class of apparatus carbon particles are used, as practically all forms of this are variations of the original White "solid back." The carbon particles now most favored are made from anthracite coal, the minute pieces of which are highly polished and are selected according to their degree of hardness. These particles are sifted through sieves having about 50 to 55 meshes per inch, and the average size of these particles is from 0.020 to 0.022 inch along the direction of the greatest dimension, although some particles in use are considerably larger. Great pains are taken to secure particles of a uniform grade, as in this way the effect of "packing" is greatly reduced. Unless these particles are of uniform size they naturally have a tendency to pack or to settle down into a compact mass, and the more solidified the carbon becomes the less readily can the current flowing in the transmitter circuit be made to fluctuate, according to the variations of the diaphragm caused by the sound waves directed against it by the voice. These granules of carbon are inclosed in a shell or casing between a front and back electrode of carbon. The vibration of the diaphragm, being communicated directly to the front electrode, varies the pressure and distance between it and the back electrode. The movement of the diaphragm is in some of these instruments dampened by springs which prevent too great amplitude of its vibration. The carbon working parts are inclosed in cups of brass, aluminum, etc. This again is usually inclosed in an outer receptacle or two-piece cup of metal, the two parts being permanently riveted or secured together so that the working parts can not be tampered with. A hard rubber flaring mouthpiece is placed in front of the speaking orifice of the transmitter, and the back is mounted upon a stand with swivel to permit its being raised or lowered in adjustment to the mouth of the speaker. The transmitter and the receiver are mounted together, either as desk sets or as wall sets. In the wall set the induction coil which is employed in the transmitter circuit is often placed in the base of the arm carrying the transmitter itself. It is also sometimes mounted upon the backboard of the telephone box. The base and arm are made of cast iron joined in such a manner as to permit of considerable vertical movement of the transmitter, so as to accommodate it to the height of the different speakers.

The induction coils are constructed and mounted in various manners by different manufacturers. In one approved type the core consists of a small bundle of fine Swedish iron wire. The primary is mounted over this, consisting of three layers of cotton covered wire. The secondary coil is mounted in two sections, bare wire being employed and the adjacent convolutions being kept apart by means of a fine thread of silk

wound alongside and parallel with the wire. Between each layer of wire a layer of paper is inserted in the process of manufacturing, so as to make the insulation complete. The machinery for the manufacture of coils in this manner is so ingenious that several coils can be wound simultaneously, the layers of paper being introduced automatically between each layer of the winding without any stoppage of the machinery, which is operated at very high speed. The use of the bare wire tends to cheapen the process of manufacture, as compared with the use of insulated wire. After the secondary windings have been finished the outside of the whole coil is usually covered with black cloth or other waterproof material, or else shellacked or varnished. The terminals of the coils are brought out to clips on the base, so as to serve as binding posts for connecting into the circuit, and they are numbered or lettered for purposes of identification in subsequent use. To give an idea of the amount of wire employed in each little coil, it may be mentioned that the winding of such coils for local battery use consists generally of about 150 turns of No. 22 wire for the primary and 6 layers of 6,000 turns of No. 36 wire for the secondary. It is by means of these induction coils that the feeble currents set up by the voice are so intensified that they are enabled to traverse long distances and overcome the resistance of many miles of transmission line without such loss as would impair them or render the undulatory current incapable of repeating successfully the operation in the receiver at the distant end.

Telephonic receivers as a general thing have varied little in outward appearance in several years, and some forms go back with little change to the original "butter stamp" adopted in the earliest years of the art. The receivers as now made consist essentially of an inclosed shell of hard rubber within which is a magnet, at the diaphragm end of which is a coil of fine wire, this solenoid consisting of very fine silk insulated copper wire wound on a spool. At one time most of the receivers employed in the United States were of the single pole magnet type, but the great majority are now of what is known as the bipolar type, the diaphragm end of the magnet carrying two solenoids instead of one, with the object of securing greater sensitiveness. In all the earlier instruments, and in many of those still in use, the binding posts of the receiver were exposed and exterior to the hard rubber shell, but in a great many of the instruments now the posts and connecting cords are carried within the shell, so that they are not so liable to work loose, and thus avoid the liability of dangerous contact on the part of the user should the incoming line be suddenly charged with "sneak" currents from railway or lighting circuits or from lightning. The troubles in the earlier type of receivers from the unequal expansion between the metal and the rubber parts are now hardly ever encountered, owing to the improvements in manufacture. The diaphragm of the receivers consists usually of very thin sheet metal vibrating in front of the magnets, and the diaphragms are either tinned or lacquered on the sides exposed to the breath to prevent corrosion from the moisture condensing on them.

For the use of all who must listen to the receiver continuously, as do the operators in the central exchanges, special receivers are made up in what is known as "watch case" or "head" form to be held to the ear by a flexible headband. Here the permanent magnets in front of which the diaphragm vibrates are of the ring type, being closed magnets, so as to produce poles on the opposite sides of their circumference. Fastened to the compound ring magnet are circular pole pieces which carry the electro-magnetic coils. The face of these pole pieces is closely adjacent to the diaphragm, as in the ordinary butter stamp receiver. The working parts are mounted in a hard rubber cap or shell and the diaphragm is clamped between the front face of the cup and the flattened ear piece, while the binding posts to which the terminals of the cord are attached are usually carried within the shell. Some forms of the watch case receiver are made up also for various uses where the employment of the longer receiver would be inconvenient.

It has already been noted that a considerable proportion of the manufactures in the telephone class were of parts and supplies, the total amounting to $2,071,895. This classification embraces a wide variety of parts, the chief items being the signaling apparatus in magneto-telephone sets and the line protectors, fuses, etc. Each magneto substation carries a pair of small gongs, between which swings a striker, forming part of an electro-magnetic system, so that the movements of the striker cause the bell to ring. The magneto generator included in the set is in reality a tiny alternating current dynamo which is operated by hand, so that when the crank is turned its armature is revolved rapidly and an alternating current is sent out over the line circuit to the central office to throw the subscriber's numbered drop on the switchboard. The substation is safeguarded against abnormal current by means of a protector placed on the backboard of the telephone set, a common form being a spark gap which consists of a pair of carbon plates, one of which is grounded, while the other is connected to the line, the plates being separated by a thin perforated mica washer. This is usually associated with a fuse or heat coil of fine fusible wire, which sometimes takes the shape of a tubular fuse, the wire being inclosed in a hermetically sealed small tube, which protects the fuse from the air and enables it to operate more uniformly. The tubular fuses are, however, used more particularly in connection with the protection of switchboards, being mounted in sets or gangs ready for insertion on the distributing board at the central exchange. In the present report fuses and lightning

arresters are as a class brought to account under a separate heading, and it is likely that many intended for telephonic use are there enumerated rather than as telephonic parts and supplies.

It will be readily understood that quite outside of the main switchboards and the apparatus in use at the subscribers' stations there is a large amount of miscellaneous apparatus which is included in "telephonic parts and supplies," and some of which even falls into other classes of manufacture. Each exchange, for example, in addition to its local and toll-line boards, is equipped with intermediate distributing frames or boards equipped with connectors to which the outside circuits are brought, so that they may be readily connected to or disconnected from the circuits within the exchange. In the case of the common battery systems there are also relay frames equipped with mounting strips for insulating individually each set of line relays, these being encased in dust proof caps or jackets. A central exchange is also provided with desks for the chief operator and the monitors and wire chiefs, each of these desks being thoroughly equipped for the supervision of the work within the exchange by the superintending force or for testing apparatus or lines immediately when any trouble arises on the circuits. The details that must be supplied in connection with ordinary interior telephone systems, intercommunicating systems, or those for simple intercommunication, are numerous also.

For many years past it has been the custom to employ the telephone for the transmission of music, sermons, speeches, etc., sensitive transmitters for this purpose being placed in the vicinity of the stage, the pulpit, or the musical performers. Separate companies have been organized for business of this character, while in Budapest, Hungary, a news system has been associated with such work. A more radical innovation or employment of the telephone owes its origin to Dr. Thaddeus Cahill, of Holyoke, Mass., who has developed within the last few years a most original and ingenious system of music production, and its distribution, by means of electrical currents over the telephone circuits. The principle of the invention is that each current of electricity from an alternating current dynamo has its own specific predetermined rate of vibration or frequency in the circuit, and that this current when brought to a telephone is there heard as a musical note. Middle C string on the piano, for example, has 256 vibrations per second, and in like manner the vibrations of current produced by the dynamo designed for that purpose number 256, and are heard as the same note in the telephone. The inventor has designed, therefore, and placed together on a common shaft 145 small alternating current dynamos, each with its characteristic current vibration, and these currents led to a keyboard can be manipulated there by the performer who, with the aid of the various transformers, or "tone mixers," is enabled to give a musical performance based wholly upon the current of these dynamos instead of upon the vibrations due to the use of reeds, strings, or pipes. The keyboard is operated by the performers just as is that of the piano or organ, or can be associated with a mechanical attachment, as in the pianola. The performers, having control of the dynamos, give not only the fundamental notes, but also the overtones or harmonics by compounding the various vibrations in such a manner as to play any chosen piece of music, and can also stamp on the sounds the quality of those from various musical instruments, such as the organ, violin, flute, etc. The plant where these electrical vibrations are generated can be connected with a large number of telephone receivers in different parts of a city, and hence the same music can be heard, simultaneously, at points miles apart. The electrical vibrations, with negligible loss in transmission, become music as soon as heard in the receiving telephone, to which is attached a megaphone horn in order to intensify the sound and enable it to be heard by several persons at once. It will be understood that these currents usually produce music only in the telephone receiver, but they can also be made audible as music in the "flame" of an electric arc lamp.

The telephone receivers and the horns attached can be exposed in full view of the audience, but are preferably inclosed or concealed in baskets of flowers, divans, ornamental urns, newel posts, etc., according to the nature of the room in which the music is to be rendered. Each receiving telephone requires a surprisingly small quantity of current for the delivery of music and a score of them will take no more than an ordinary incandescent lamp. The first commercial plant installed in New York city driven by a motor of 200 horsepower has an estimated capacity of from 15,000 to 20,000 subscribers, each furnished with a telephone that can be heard by a large audience. The music has been transmitted from the original plant at Holyoke, Mass., as far as Springfield, Mass., and New Haven, Conn., with success, but it is intended that each "central" shall be restricted to local delivery of its music. In addition to the large sets of apparatus for central station music purposes, the owners of the patents are manufacturing smaller isolated plants intended for separate use, and giving music, as desired by the individual performer, in exactly the same manner as an isolated light and power plant.

An ingenious piece of apparatus which has been introduced within the past year or two for use in connection with the telephone is the Poulsen telegraphone, the object of which is to furnish a record of the speech received over the telephone. Dispute often arises as to the exact nature of telephone conversations, and litigations have arisen on account of the discrepancy between the alleged statements of the interlocutors.

In the telegraphone the principle employed is that of recording upon a narrow traveling steel strip, or fine wire, the message or speech as received. As now manufactured and actually in use, the telegraphone embodies two large spools mounted on top of a small box which is equipped with an ordinary telephone transmitter and a pair of telephone receivers. From one spool to the other, standing 6 inches apart, runs a steel wire $\frac{1}{100}$ inch in diameter. Standing between the spools, on a vertical support or arm, are two small electro-magnets facing each other, about $\frac{1}{16}$ inch apart. When the conversation is going on, the magnets are switched into circuit, the wire is set in motion between the two spools, running from one to the other, and the vibrations of the voice as received from the distant transmitter are communicated electrically to the magnet coils. As the wire travels between the magnets it becomes magnetized with an intensity and a polarity corresponding to the strength of the particular sound vibrations, which correspond to the waves of electric current at that instant. When the conversation is finished, and the record is therefore complete, the spools are reversed and the wire reeled back. When it is required to listen to the conversation or to the message which has been taken by the telegraphone during a man's absence from his office, the receiver is put into circuit with the magnets and the wire is once more reeled off from one spool to the other. The magnets and the magnetic wire now act in such a manner that the coils are electrified, strongly or weakly, just as they were under the influence of the original undulatory waves of current created by the voice vibrations. In this manner the varying vibrations stamped magnetically on the traveling wire are communicated by it to the receiver and the conversation or message is reproduced by the receiver. The wire travels at the rate of about 10 feet per second. In addition to serving as a record for telephonic messages, the telegraphone is made to do also the work of a phonograph for receiving dictation; the wire with the dictation being run through again afterwards by the typewriter, who places the receiver to her ear for the purpose. In this manner a large amount of dictation or correspondence is provided for, as there are about 2 miles of wire on each spool. Another feature of the apparatus is that the reversal of the apparatus so as to secure the record cleans the steel wire of the record it has received. The passing of the wire before the electro-magnets "wipes off," so to speak, the magnetic impression which the wire had received originally. The whole apparatus has been developed into simple, compact form, and while not yet in extensive use, must be regarded as a part of the resources of the telephonic art available at the time of the present report.

During the past year or two submarine signaling based upon the use of the telephone has been introduced and a number of light-houses and steamships have been equipped with the system, which is of American origin, owing its perfection to Prof. Elisha Gray and Mr. Arthur Mundy, of Boston. The principle embodied is found in the fact that sound vibrations travel very easily in straight lines in the water—at about four times the speed that they do in air—and can be heard at a considerable distance if there is apparatus upon which the vibrations can impinge.

In the submarine telephone signaling apparatus now manufactured, a small tank is attached to the inner side of the skin of the vessel. This tank is filled with a chemical solution, denser than water, and contains a microphone. A sound reaching the ship's side through the water, passes into the solution in the iron tank and the vibrations impinge upon the sensitive microphone, acting as do the corresponding vibrations of the voice in the transmitter system of a talking circuit; from there the currents are carried to the receiving station in the pilot house, or other appropriate place, such as the ship's bridge, and are there heard by the telephone receiver. The receiving box is equipped with two telephone receivers instead of one. By holding first one receiver and then the other to his ear, the pilot, or navigating officer, can tell on which side of his vessel the submarine bell is located that is giving notice of danger, for the reason that the sound vibration travels in straight lines and therefore the direction can be very accurately determined. The same method applies to the indication of the location of two steamships during a fog, as both can tell the direction of travel and thus modify their course to prevent accident. In a report to the United States Navy Department, Lieutenant-Commander Walling has stated that the direction of a submarine bell can thus be determined by the telephone within one-eighth of a point on the mariner's compass. More definite data as to the commercial use of the invention are afforded by the fact that the signals of Nantucket, Fire Island, and Sandy Hook lights and light-ships have been picked up by approaching steamers from Europe at distances of 4 miles, the bell code numbers being known to the officers of the vessels. A great deal of work was done with the system during the year 1904–5, and at the time of the preparation of this report 19 light-ships on the Atlantic coast, about 125 steamships, and 2 American battle ships had submarine signal equipments. This American invention has also been introduced abroad and placed upon English, French, German, and Dutch light-ships.

A composite form of apparatus has recently been introduced, called the "telegraphone." It will be noticed that this name is somewhat confusing, as it has already been adopted for the Poulsen recording telephone apparatus previously described. This instrument is in all outward appearance similar to the

45254—MFG 1905—PT 4—08——15

ordinary telephone, but it is not intended for telephonic use in the ordinary sense of the word. Through an adjustment of the railway telegraph circuits the apparatus can be attached to regular telegraph wires in such a manner that conversation, as well as the transmission of signals, can be carried on without interference by the calling devices with the Morse relays. The railroad telegraph apparatus can thus render double service; as the composite set avoids the cost of stringing an overhead circuit which is necessary when separate telephones are used by the railroads. It is stated that several hundred complete sets of this apparatus were manufactured during 1904. It should also be pointed out that simultaneous telegraphy and telephony over the same circuit has long been practiced in this country and in Europe, with methods and apparatus that are described in all the standard books dealing with the transmission of intelligence. The use of the telephone principle in railway telegraph signaling was also adopted by Mr. Edison several years ago in his well known "phonoplex."

Telegraph apparatus.—Table 15 shows the production of telegraph instruments, switchboards, and parts and supplies, reported in 1900 and 1905.

TABLE 15.—*Telegraph apparatus—number and value: 1905 and 1900.*

STATE.	Total value.	INTELLIGENCE (KEY, SOUNDER, ETC.).		Police, fire, district, and miscellaneous (value).	Wireless telegraph apparatus (value).	Switchboards, and parts and supplies (value).
		Number.	Value.			
United States, 1905..	$1,111,194	76,826	$187,744	$592,070	$114,050	$217,330
1900..	1,642,266	199,410	[1] 354,212	1,231,167	.....	56,887
States, 1905:						
New York.....	412,106	24,756	96,339	145,438	8,500	161,829
All other states.....	699,088	[2] 52,070	[2] 91,405	[3] 446,632	[4] 105,550	[5] 55,501

[1] Includes instruments to the value of $5,300, for which number was not reported.
[2] Includes states as follows: Illinois, Maryland, New Jersey, and Oregon.
[3] Includes states as follows: Illinois, Maryland, Massachusetts, Ohio, and Wisconsin.
[4] Includes states as follows: California, Colorado, District of Columbia, and Massachusetts.
[5] Includes states as follows: Maryland, Massachusetts, Missouri, Nebraska, New Jersey, and Wisconsin.

It will be noticed that there is an apparent falling off of at least half a million dollars in the value of telegraphic apparatus for 1905 as compared with 1900; the value in the earlier year being $1,642,266, whereas the last census year it was reported as only $1,111,194. This decline was perhaps more apparent than real, as in recent years the larger telegraph systems have shown an increasing disposition to make and repair their own apparatus rather than to purchase it from manufacturers in the open market. It is obvious that throughout the country the mere wear and tear on apparatus sending and receiving a hundred million messages a year, would require considerable outlay for renewals, even if no new offices were equipped. As a matter of fact, a large number of new telegraph offices of an extensive character have been equipped in recent years, calling for apparatus in quantities at least equal to those required at earlier periods in the art. To take a typical case, the Western Union telegraph system reported for the year 1904 the equipment of 338 new offices and no fewer than 356 in the year 1905, while during the two years referred to large offices were remodeled or reequipped at such important centers as Boston, Philadelphia, Cincinnati, Cleveland, and St. Louis. Moreover, in the year 1904 dynamo current was substituted for chemical cell main batteries in fifteen important centers of the same corporation, involving in the change extensive renewal, adjustment, and rearrangement of apparatus.

The newer apparatus in the telegraphic field includes that employed for what may be called high-speed printing purposes, intended to supplement or supersede the work of the manual operators who still transmit with the lever key the great bulk of American messages. The quantity of apparatus of this "machine" character manufactured is still quite small, but it would seem that the inventions in this field must result in making machine telegraphs play a conspicuous part in the telegraphic art. It has been said by one of the most prominent managers in the telegraphic field that the advances in the direction of developing and perfecting printing telegraph systems, adapted to all the requirements of modern service, leave no doubt as to the employment of such systems in the domain of commercial telegraphy. The most conspicuous systems of this character utilized to any degree in the United States are those of Buckingham, Rowland, Murray, and Delany.

In the Rowland system the basic principle is the employment of alternating current, which, dominant in the domain of light and power, is ideal also for the long distance transmission of intelligence. In order to transmit the signal, however, the alternating current is modified. For each signal the base, so to speak, is a block of alternating current, consisting of 11 half waves which are modified by the reversal of any two. In other words, the sending of signals is actually accomplished, not by supplying the line with current at the moment the signal is being transmitted, as in ordinary telegraphic methods, but by cutting out certain of the alternating current waves. Hence one or more of the signals can be made to consist of a combination of suppressed half waves, the signals so produced being then translated automatically into printed characters. In this manner, and by grouping the waves so as to permit of entirely different and independent signals being sent from four typewriter keyboards, each of the four transmitting operators employed can cut out four different wave combinations and thus send as many different signals over the line in a single second. Forty words per minute is given as a fair rate of speed for a practiced operator with this system, and as the system

can be duplexed, eight times that number, or 320 words in all, can be sent over a telegraph wire and printed in one minute. The late Prof. H. A. Rowland developed his system so that the letters of the alphabet, figures, and some extra signs are printed automatically in such a manner that each operator, by writing on the ordinary typewriter keyboard, prints on a page 8 inches wide at the other end of the line over which he is sending. These pages of printed matter have the general appearance of an ordinary sheet of typewritten matter, with the letters and figures appearing in clean cut block type.

In the Murray printing telegraph system the typewriter is again employed—the messages being mechanically both transmitted and recorded with it. Perforated paper tape is first prepared by means of a keyboard mechanism, the punches corresponding with letters and figures, and the tape is then passed through a Wheatstone transmitter, which, at a high rate of speed and operating automatically, sends out the signaling currents to the distant receiving station. These currents are utilized not to actuate the printing mechanism directly, as in the case of the other printing telegraph systems, but to produce a second perforating tape at the receiving end—this tape controlling mechanically a typewriter in the same manner as the perforated rolls of music operate mechanical pianos or organs. The Murray system affords a high rate of transmission on the wire and a high rate per operator, but is subject to the criticism that both the sending and the receiving stations employ a perforated tape, which in actual practice involves delay, especially in the case of errors or damaged tape. A maximum theoretical speed for the Murray apparatus working simplex is given of 96 words per minute and a practical speed of 120 messages of 30 words each per hour. Working duplex this system is credited with a theoretical speed of 192 words per minute and 240 messages per hour.

The Buckingham system is the first really rapid long distance page printing telegraph that has ever been introduced successfully, and it has been in use for a considerable period of time on some of the longest circuits in the United States. The distinguishing features of the invention consist again of a typewriter perforating apparatus for preparing the paper tape for transmission purposes, and the printing mechanism at the receiving end of the line. The perforated paper tape is run through the Wheatstone transmitter, which forwards the signals automatically to the distant receiving station; there they are received upon a Wheatstone relay and thence repeated into the local circuit mechanisms; these are of a novel and ingenious character, and so operate that the current distributing apparatus and the type wheels print messages upon regular telegraph blanks. These blanks encircle a tube, and when the printing of a message begins, one of them is slid edgewise upon a brass tube which serves as a support. When the blank has been printed, it is slipped off quickly to one side and a fresh blank takes its place. The message when thus printed is spread out by cutting it open, when it can be forwarded immediately to the addressee. The four-type wheels in the Buckingham system carry 32 characters, inclusive of the letters of the alphabet and punctuation marks, this special alphabet having been devised by Mr. Buckingham as adapted to the system. It is subject to the general objection of requiring a preliminary perforated tape, but on the other hand the messages received are printed ready for delivery, a notable point in total speed of transmission. In messages over Western Union circuits between New York, Chicago, or Buffalo, during six or seven years of operation, a working capacity of 200 messages per hour operating duplex has been noted. A modification of this system has been introduced in the Barclay method, which embodies a form of electrical typewriter of great sensibility and rapidity in action, and a comparatively simple printing mechanism so devised as to meet more fully the service requirements, and aiming at the same time to improve the legibility and general appearance of the printed message as sent out to the public. It is said that with the Barclay system a speed of at least 100 words per minute has been secured.

The Delany rapid telegraph system includes a perforator machine which may be operated by the ordinary Morse key at the highest speed of expert operators. With two such machines an automatic transmitter may be fed with perforated tape, and messages sent over the line at a rate up to the highest ability of the typewriter operator receiving at the distant end. Thus, with two perforating operators working at 20 words per minute, the automatic transmitter will deliver 40 words per minute in improved Morse to the receiving operator, so that the capacity of the circuit may be doubled, and a duplex become equal to quadruplex in output with six operators as against eight. The quadruplex wire may also be made to carry double the number of messages with twelve men doing the work of sixteen. The speed is limited only by the impulse-conveying efficiency of wires, or the delivery of impulses of sufficient power to make a mark with iron recording wire on the chemical tape by electrochemical action, permitting of ready transcription by the receiving operator, who has to translate the marks on the tape. The perforated message is made up entirely of dots, all impulses having the same time value, and each succeeding one being of opposite polarity to the one before it. The time between the positive marking impulses and the negative, cutting off, or spacing impulses determines whether the character is a dot or a dash in the Morse alphabet. As a matter of fact the perforator can be worked by an ordinary keyboard transmitter, so that any typewriter can perforate the sending tape without even knowing the Morse

alphabet. The receiving machinery is under the control of the transmitting operator, so that it may be stopped at any instant. The chemical receiving tape is only slightly damp and is wound up on wheels as it passes through the machine. It is not handled by anybody, being drawn in short lengths in front of the typewriter as the transcription is effected by means of a mechanical contrivance which is under the control of the typewriter's foot. It is stated that the transmitting apparatus is capable of running up to a speed of 10,000 words per minute, and that 8,000 words, or 2,500 impulses, a second have been recorded over an artificial circuit.

A great deal of time and attention has been devoted by inventors to the development of writing telegraph systems, and considerable ingenuity has been displayed in their manufacture. One system is in use in the United States at the time of this report and is being continuously developed. It depends, broadly, upon the principles of the parallelogram of forces, so that by compounding the movements of a point in two directions, one at an angle to the other, the actual path described by the point is the result of the two separate movements. In the telautograph, as thus worked out, the receiving pen operates under the variations of the magnetism of two electro-magnetic systems at right angles to each other, and reproduces with very close approximation the handwriting of the operator at the transmitting end in accordance with the motion of his pen or stylus. At the transmitting end a pencil is attached by rods to two lever arms which carry contact rollers at their ends, these rollers bearing against the surface of current carrying resistances connected with the sources of direct current supply. Hence the writing currents pass through the resistances to the rollers and thence to the line wires, so that as the stylus is moving in the act of writing the relation or position of the rollers in respect to the rheostats is constantly changing, and hence currents of varying strength are let through. Satisfactory operation is obtained with currents of a pressure from 80 to 250 volts, and the ordinary 115-volt current from incandescent lighting circuits is quite suitable. A master switch at the transmitter makes the necessary changes in the circuits and cuts out the mechanism when it is not in use. There is also a device for shifting the transmitter paper a distance of one line of ordinary writing, just as the paper is carried forward on a typewriter frame. The writing space is about 2 inches long and 5 inches wide, and allows for four or five lines of writing. When the sheet has been filled up, fresh paper is readily brought into position at the transmitter and with equal ease at the receiver. At the receiving end the apparatus for automatic writing is highly ingenious, particularly with regard to the supplying of ink and securing an easy, smooth movement of the transcribing pen. This apparatus has been introduced in the United States coast defence service for sending ballistic data from position-finding stations to the gunners. A special type of the telautograph has been manufactured for and adopted by the United States Signal Corps for fire-control communication. Commercial service is represented more specifically by its employment in hotels and clubs, communicating between restaurant and kitchen, for example.

Wireless telegraphy, since the last report on electrical manufacturing was made, has entered into such a sphere of importance and usefulness, both in peace and war, that its treatment has already become the subject of national and international control. Inventors in this field have been numerous, not only on both sides of the Atlantic but in South America and Japan, and the amount of wireless telegraph business now transacted is quite large, thousands of messages being daily transmitted through the ether, chiefly between ships and shore, but also between stations upon land. All of these wireless telegraph stations depend upon wire towers or antennae, carried high in the air in order to give off to, and to receive from, the ether the electrical impulses impressed upon it by the transmitting system. The wireless telegraph stations along seacoasts or on shipboard already number several hundred, and every navy and important line of commercial steamships has its complete system of wireless telegraph apparatus. The introduction of the system has already been carried so far that it has been put on board some of the larger boats of the American fishing fleets. The whole coast line of Europe is dotted with wireless telegraph stations, and a chain of stations also extends along considerable portions of the American coast as well as up the St. Lawrence river. The equipment of these systems with towers and high tension generating apparatus has developed a new field of manufacture, but only the figures of specific telegraph apparatus are embraced in the values given in this report under "telegraphy," including the special transmitters, receivers, coherers, keys, and other features. The generating plants for stations of high power with a "striking" radius of hundreds of miles are now equipped with alternating current generators and transformers of considerable horsepower. The distance of the message bears a fair ratio to the amount of electrical energy employed in sending out the high frequency impulses to the atmosphere.

The leading systems of the apparatus in use in the United States are the Marconi, the Slaby-Arco, the Braun, and one or two others of European origin; but there are several highly ingenious and successful American systems, notably those of Fessenden, De Forest, Massie, and Stone, all of which have been put into commercial operation. A principal element in the wireless telegraph systems is the device for intercepting the etheric impulses so as to convert them into signals. A leading type of coherer apparatus consists

of a small pencil-like glass tube filled with metallic filings, which are caused to cohere by the incoming impulses and which are usually made to decohere by means of a tapper in the local circuit. This little tube receives the successive impulses and records them with auxiliary appliances, or renders them audible in a telephone receiver. The coherer by its variations operates a very sensitive relay, with an ink-recording device, by means of which the message is registered in the Morse alphabet. Some of the coherer systems are automatic in their operation. The rate of signaling with the filings coherer is comparatively slow, being limited to about ten or fifteen words per minute, on account of the sluggishness and mechanical inertia of the various parts. The distance of operation with this coherer also seems to be somewhat limited. A typical autocoherer system is that which has a telephone receiver in circuit, the variations of the current producing sound in the telephone receiver of long or short variation, corresponding to dots and dashes of the telegraphic alphabet.

Another form of autocoherer, or detector, is that devised by Marconi, based upon the principle that electrical oscillations affect the magnetic changes in iron, enabling them to occur more rapidly. An endless belt of thin wire about 12 inches long revolves on a pulley operated by clockwork, and passes through a spool on which are wound two coils of fine wire. The outer wrapping or coil is part of a circuit in which is included a telephone receiver, while the inner coil of wire is connected in series with the vertical wire tower or antennae. Two horseshoe magnets having their like poles adjacent to each other are placed in proximity to these coils, and while normally the changes of the magnetism in the traveling wire in proximity to the magnets are not sufficiently rapid to set up currents in the coil, the conditions are different when rapid electrical oscillations occur in the inner coil, these being accompanied by correspondingly rapid momentary changes in the magnets of the traveling core or wrapping of thin wire. The consequently rapid variation of the magnetic lines, or field of force, in the traveling wire set up momentary currents that are detected or heard as sound in the telephone receiver. It appears that a speed of 25 or 30 words a minute can be obtained in practice with the detector, thus doubling the rapidity obtainable with the filings coherer.

Another form of receiving apparatus is the Fessenden detector, which consists of a small insulating vessel, wherein is placed a weak solution of nitric acid. Down into this solution penetrates for a short distance a very fine platinum wire, and another platinum wire enters the acid from the bottom of the vessel. This device, or detector, which is called a liquid barretter, is connected for receiving between the vertical wires, or antennae, and the ground. The principle embodied is that all the resistance in the conducting medium is concentrated within a short distance of the point where the fine platinum wire enters the acid. Hence all the temperature effects are local or take place inside a hemisphere of comparatively small radius. The heating effect of the small battery in the shunt circuit normally increases the resistance of that circuit, but the resistance is broken down by the incoming electrical oscillations, and the variations of the current strength due thereto are recognized, in the telephone receiver employed, as dots and dashes. According to Mr. Fessenden, the action of this detector is not electrolytic, but thermic. Apparatus of a similar character for wave detection has been employed in the De Forest system, the detector being a very fine wire extending into the liquid contained in a small cup, with another wire running through the base of the cup. The liquid in the cup is a slightly acidulated solution. The principle, according to Doctor De Forest, being that the action is electrolytic, the current from the small battery sets up a further electromotive force of polarization which the arriving oscillations disturb, thus securing the desired audible result in the telephone receiver.

A more recent and highly ingenious form of apparatus of De Forest invention is that known as the "audion." This receiver for wireless telegraphy consists of a low voltage incandescent lamp with carbon filament, connected to a source of current consisting of a battery of dry cells and a rheostat for varying the current at will. Within the bulb of the lamp are placed two platinum wings, one on each side of the filament. A second set of dry cells is connected between the positive end of the filament and the platinum, the latter being connected to the positive pole of the battery. When electrification is produced in the neighborhood of the incandescent filament, a positive leakage discharge current will pass from the platinum wings through the attenuated gas in the bulb to the filament, and the conductivity of the gas between the wings and the filament increases rapidly with the increase of the heating current through the filament. When the audion is connected, either inductively or conductively, in an oscillation circuit of a wireless telegraph receiver, it forms an extremely sensitive detector of ether or Hertzian waves, giving responses or indications in the telephone receiver several times louder than any other known form of wireless receiver subject to the same impulses. It is stated that the device is extremely selective in its behavior with reference to waves of different lengths, and can be closely tuned with the syntonizer. By regulating the heating current—the potential between the wings and the filament, or the distance between these—the audion is made to a great extent selective for itself to the received impulses. It gives no evidence of fatigue under any conditions of use, requiring no adjustment in the receiver, and needing no protection from the violent impulses of the transmitter at its own station, as com-

pared with the sensitiveness of the receivers of the electrolytic type, which are said to be completely upset by one such violent impulse unless protected by a shunting switch.

As will be noticed from Table 15, a large proportion of telegraphic apparatus in 1905—in fact, one-half, $592,070—is comprised under the head of "police, fire district, and miscellaneous." The miscellaneous telegraphs in this group are not numerous, but the other three classes are important and are in constant demand. During recent years there has not been much change in any of them, except in the association with the older forms of telephony, which is under trial in various cities for fire and police purposes. The district messenger box is still to be found in most large modern buildings, but no essential change has been made in its mechanism or in the variety of the calls that may be effected through it. Here again the telephone has had some influence, and in more than one modern form of district messenger box an attempt has been made to add the telephone to the apparatus as a means of increasing its efficiency. The general subject of municipal telegraphs, including fire and police systems, will be found treated in great detail in the special report issued by the Bureau of the Census, entitled "Telephones and Telegraphs: 1902."

Insulated wires and cables.—Table 16 gives the value of insulated wires and cables manufactured as reported in 1900 and 1905.

TABLE 16.—*Insulated wires and cables—value: 1905 and 1900.*

STATE.	Value.
United States, 1905	$34,519,699
1900	21,292,001
States, 1905:	
Connecticut	2,156,369
Illinois	3,666,313
Massachusetts	1,091,522
New Jersey	8,234,885
New York	10,911,897
Pennsylvania	2,885,052
Rhode Island	5,122,464
All other states[1]	541,197

[1] Includes states as follows: California, Indiana, New Hampshire, Ohio, Oregon, and Wisconsin.

A total value of $34,519,699 was returned for the production of insulated wires and cables by 61 factories during the census year 1905. The industry was well distributed throughout the country, being carried on in 13 different states. The chief center of the industry is New York, which, with 12 factories, reported an output valued at $10,911,897; New Jersey follows, with 7 factories and an output valued at $8,234,885; and Rhode Island is third with an output valued at $5,122,464. As will be noted these 3 Eastern states accounted for considerably more than half of the total output, and if the product of Connecticut, $2,156,369, be added, it will be seen that these 4 Eastern states accounted for more than five-sevenths of the whole output of the country. The two other states conspicuous in this line of work were Illinois and Pennsylvania, the former with an output of $3,666,313, and the latter with an output of $2,885,052. The entire production of the country is reported by value only, the sizes of wire being so numerous and the complexities of their manufacture into cables being so intricate that no definite figures could possibly be secured as to the length in feet or the quantity in pounds. Every branch of electrical industry requires large amounts of insulated wires and cables. Every telegraph office and telephone exchange employs large quantities of such wires and cables. Every house or factory or office building wired for electric lighting and power receives and distributes its current through insulated conductors. Every motor car is heavily cabled, while every dynamo and motor is built up with insulated wires and cables. Some idea of the consumption of this class of material in one field alone may be formed from the fact that at the close of the year 1905 the companies constituting the Bell telephone system had in use not less than 320,000,000 pounds of copper wire, which would represent a value of copper alone of about $60,000,000. This copper is largely made up into cables of a permanent type, carried upon no fewer than 8,000,000 poles, and through 95,000,000 duct feet of underground conduit. An equally impressive idea of the consumption of cable is afforded by the fact that the electric zone of the New York Central and Hudson River Railroad has in its transmission circuits 1,500,000 pounds of copper in cables, and for the transmission and subsequent distribution from the substations a total weight of 3,000,000 pounds of cable, a large proportion of which is heavily insulated. In this electric zone there are 16 miles of cable conduit, 97 miles of cable in the conduits, 344 miles of cable upon poles, 3 cable towers, and 383 splicing chambers, where the short lengths of cable are united and made continuous throughout the system. Another striking fact is that a single telephone switchboard of the large modern type contains as much as 10,000 miles of insulated wire.

Underground cables in the field of electric lighting and power work are manufactured in three main classes: High tension, multiple, or single conductor cables of relatively small current carrying capacity, for operation under working pressures of from 2,500 to 25,000 volts; low tension single conductor cables of large current carrying capacity, operating under electric motive force of about 650 volts or less; and return cables of large current carrying capacity, but operating only under a pressure corresponding to the voltage "drop" in the return feeders. The third class has hitherto received little attention, and, in fact, bare copper cable has generally been installed, but the desirability of the use of insulated cables of this class has been approved and recognized in the last few years. High tension cables of the first class have developed

from the stage where merely rubber was used for insulation up to the time of the present report, when rubber, varnished cambric, saturated tape, and paper insulation have all been brought to a high state of perfection for this work. Rubber is used only where local conditions seem to demand an insulation that is impervious to moisture, so that in case the outer protected lead sheath should be punctured the cable itself need not necessarily fail. The superintendent of motive power of the Interborough Rapid Transit Company, of New York city, points out that where cables have to be installed in conduits that are under water part of the time or on the beds of rivers, etc., the extra investment for the more costly rubber insulation is justified, since in case of a leak in a submarine or submerged cable lead sheath it usually becomes a total loss if insulated with paper or non-moisture proof material, whereas good rubber lasts indefinitely under water. For pressures above 22,000 volts some form of varnished cambric or impregnated cloth is preferred in place of paper, owing to its higher resistance to puncture for a given thickness. Conservative practice in cable manufacture with paper insulation for standard working pressure of 3,000 volts requires on a cable ranging from No. 000 to 300,000 circular mils a paper insulation thickness of $\frac{5}{32}$ inch, with $\frac{1}{64}$ inch thickness of lead in a single conductor cable up to $\frac{3}{64}$ inch in a three-conductor cable. In heavier cables with paper insulation, as, for example, 1,250,000 to 2,000,000 circular mils, with the same working pressure of 3,000 volts, good practice requires an insulation of paper of $\frac{3}{32}$ inch, with $\frac{3}{64}$ inch thickness of lead in the outer sheath.

As already noted, a very large amount of insulated cable manufactured is employed in telephonic work. The conductors in most telephone cables are Nos. 19, 20, or 22 B. & S. gauge copper wire. The single wires are first insulated with paper wrapped spirally on the wire, providing in good insulations four thicknesses of paper between the wire and the outside of the insulation. It is so arranged that in doing this work one of each pair of wires receives two wrappings of gray paper, or two wrappings of red paper, or some other contrasting color, so that when the wires are twisted together into pairs each has its distinctive color. It can be readily understood that this means of identification facilitates the work when the cable is put into use. After the wires have been twisted in pairs they are laid up in a coring machine consisting of a series of drums and spindles, revolved in such a manner that at the end of the operation a cable core has been built up which has its alternate layers of wire put together in the same direction and the intermediate layers put on in the opposite direction, the object being to secure a non-inductive core. After this core has been made, it is given a wrapping of heavy manila paper and is then dried very carefully in ovens, in order to secure high insulation and low electrostatic capacity in the finished cables. The next process is that of encasing the core in a lead sheath. Melted lead is put into lead presses, allowed to cool, and subjected to enormous pressure. It assumes a plastic state and is squeezed out around the cable core, where it assumes a solid state and forms a continuous unbroken sheath upon the cable. The lengths of cable are then tested and are ready for shipment on drums to the point of use. The great advantage of paper insulated cable is that its low electrostatic capacity makes it much less expensive than other types. The rubber cable requires three times as much copper conductor as the paper cable, hence as the capacity increases with larger conductors the rubber insulation becomes more expensive than paper, on the basis that rubber cable has about three times the electrostatic capacity of paper cable. The object of making the telephone cables in twisted pairs is to avoid cross-talk induction, and the length of the twist varies from 3 to 6 inches.

Several years ago a type of telephone cable embodying most of the essential requirements mentioned above was developed for the American Bell Telephone system. This "conference specification" was as follows:

Sizes.—Number of pairs, 25, 30, 50, 60, 100, 120.

Conductors.—Copper 19 B. & S. gauge, conductivity 98 per cent of pure copper.

Insulation.—Dry paper.

Conductor arrangement.—Twisted pairs, length of twist not over 3 inches.

Core.—Laid up in successive reversed layers, with a lay of at least one turn in 2 feet.

Seal.—The end of each length sealed with insulating material for at least 2 feet.

Sheath.—The cores to be inclosed in a lead pipe $\frac{1}{8}$ inch thick, having at least 2.9 per cent of tin.

Electrostatic capacity.—Shall not average more than 0.080 microfarads per mil.

Insulation.—One hundred megohms per mil.

Guarantee.—Capacity shall not increase, nor insulation decrease, for five years.

There have been some modifications suggested by experience during the past few years; but the chief one, perhaps, is that which has carried the sizes of cable from 120 pairs up to 200 and even 400 pairs, the economy of the larger cable being considerable. A further modification in telephone cable is due to Dr. M. I. Pupin, who has introduced a method of locating inductance coils in telephone cables in such a manner as to assist the voice currents and prevent the deformation of the waves upon which accurate transmission depends. If the electrical waves have a length of 15 miles, and these balancing inductance coils are placed at such a distance, the current will be assisted by them in its travel and the waves will retain their proper shape, enabling the receiver to give forth the transmitted speech or sound with a minimum loss of volume or quality. Pupin cables have already come into extensive use and, it is understood, have been installed

for service between such points as New York and Philadelphia, enabling the circuits to be placed underground the entire distance.

While reference has been made above to india rubber as a substance that may be said to come in physical competition with paper in the manufacture of insulated wires and cables, it should be added that gutta-percha also is in use to a considerable extent as a gum of the highest insulating quality and as one which is suitable for such work virtually without any preparation beyond that which is necessary in purifying it from foreign materials. Gutta-percha has long been regarded as the standard insulation for submarine cables, but, as until recent years very little submarine cable was manufactured in this country, gutta-percha cable was not regarded as a typical American electrical product. Within the last decade, and particularly within the last five years, these conditions have changed. As late as the time of the Spanish-American War a deep-sea cable had never been manufactured in the United States, prominent as was the association of this country with the very first cable enterprises to span the Atlantic ocean. Through the insistence of Gen. A. W. Greely, Chief Signal Officer, U. S. A., and his faith in the ability of American manufacturers, the first cable was made and laid for war purposes by Col. James Allen of the United States Signal Corps, at Guantanamo, Cuba. Over this cable all the war news was flashed directly to Washington from the seat of operations, and the final victory at Santiago was reported to the White House within an hour of its occurrence.

Another important enterprise and development in this direction occurred a few years later, when in 1902–3 an American company manufactured and laid for the Mexican Government 500 miles of rubber submarine cable in the Gulf of Mexico. This cable is 500 miles long, weighing 1,300 tons, with a deep-sea diameter of 1 inch and a shore-end diameter of twice that size. This cable after manufacture was loaded in four tanks in the cable ship and was laid successfully, since which time it has been in continuous service.

The most extensive and interesting achievement of American manufacturers in this field associated with the United States Signal Corps has been the creation of a new system of over 2,000 miles of American-made cable for the Philippine Islands. This system places Manila in immediate communication with the most distant islands of the archipelago and renders feasible the swift administration of civil and military affairs from the seat of government. A corresponding system of equal magnitude laid with seamless rubber cable of American manufacture is that which has been created by the United States Signal Corps in Alaska, where the network in 1904 included 2,079 miles of cable.

Conduits.—Table 17 shows the value of electric conduits reported in 1900 and 1905.

TABLE 17.—*Electric conduits—value: 1905 and 1900.*

	Total (value).	Interior (value).	Underground (value).
United States, 1905	$2,416,245	[1] $2,153,069	[2] $263,176
1900	1,066,163	([3])	([3])

[1] Includes states as follows: Connecticut, Massachusetts, New Hampshire, New Jersey, New York, and Pennsylvania.
[2] Includes states as follows: California, Connecticut, Indiana, and New York.
[3] Not reported separately.

Unless wires are carried overhead upon poles in the form of single conductors or cables, they are now almost invariably installed in conduits underground, or in interior conduits if used within the buildings. The present report gives a total of $2,416,245 for both classes of electrical conduit, divided into two quite unequal portions, namely, $2,153,069 for the interior class of work and $263,176 for underground conduits. No division was made of this product into the two classes in the census of 1900, when the total reported was $1,066,163. On the other hand, no attempt has been made this time to secure any record as to the mileage of duct feet or of the straight conduit. In the census of 1900 only about half the amount reported was accompanied by statistics from establishments able to report quantities, and the data proved so inconclusive as to render it inadvisable to make a further attempt to determine quantities; although this data would be relatively easy to obtain in connection with interior conduits, as compared with those for underground work, the latter being often of a multiple character. Hence a linear foot of conduit may comprise anywhere from 2 or 4 to 12 or 20, or even more, feet of duct.

In 1905 the production of interior conduit was reported from 10 establishments and of underground from 5, located in 8 states. The statistics in detail by states can not be shown separately without disclosing individual operations. The chief centers of conduit production were, in the order named, Pennsylvania, New Jersey, New York, and Massachusetts, these 4 states producing $2,298,090 of the $2,416,245 for the entire country. The product elsewhere throughout the country was negligible. So far as underground conduit is concerned, it is not to be understood that this embraces all the conduit employed during the year in this class of electrical construction, as material is often used or is made up on the spot which does not come into any regular manufacturing category.

Reference has been made to the statistics of terra cotta and fire clay conduits and electric porcelain supplies, included as part of the industries of that character and reported separately. These are not included in the figures of Table 17 in any manner. As already intimated, however, the total for interior conduits may be taken as representing the full factory value of the product, as "interior" conduit, so called, is made specifically for such use. At the same time it

is not unusual to employ an unlined or uninsulated bare iron pipe of merchant size for some classes of interior work, and this pipe, not being made exclusively for interior electrical purposes, is of course not regarded as coming within that branch of manufacture. The rules of the national electrical code provide that such unlined pipe can be used for wires and cables having a heavy braid on the outer covering. Pipe of this character, as will be readily understood, can also be safely employed for runs of telegraph and telephone or annunciator circuit not exposed to any danger of cross connection or short circuit with other wires carrying heavier currents for light and power.

The interior conduit included in the present statistics consists generally of two classes—insulated metal, such as iron and steel pipe, which has a coat of some enameling and insulating substance, and conduits woven of textile fabrics and impregnated with insulating compounds. In insulated metal conduits the enamel or protective lining is firmly attached to the pipe so as to form an integral part of the surface, and does not break or crack when a length, at a temperature of 212° F., is uniformly bent to an angle of 90° with a curve radius of 15 inches in pipe of 1 inch or less and a radius of fifteen times the diameter of the pipe for larger sizes. This insulated lining is at least $\frac{1}{32}$ inch in thickness, does not soften so as to flow at temperatures below 212°, and is sufficiently resisting to other tests to make it thoroughly satisfactory for protective insulation in the walls of buildings or for placing in elevator shafts and other exposed places. A great deal of ingenuity has also been devoted to the subject of conduits of textile fabrics, and these without protection, or with a metallic sheath, constitute a very large proportion of the interior work now done in the United States. It is now the practice to install the entire conduit system of a new building in advance of wiring, as the building itself progresses, and it is virtually completed before a single wire or cable is drawn in, the ends of the conduit runs being brought out at each floor or room so as to connect with the junction boxes, panel switchboards, and the service wires to the consumption devices, such as lamps, motors, heaters, etc. Some of the wiring is still done in wooden or metal moldings, but this of course is no part of the conduit system, which is now regarded as essentially an integral part of a new building, as the water or gas pipes.

Annunciators and clocks.—Table 18 gives the number and value of annunciators for 1900 and 1905.

TABLE 18.—*Annunciators—number and value: 1905 and 1900.*

STATE.	Number.	Value.
United States, 1905	93,140	$185,870
1900	57,022	[1] 224,885
States, 1905:		
New York	22,019	61,959
Pennsylvania	22,220	40,824
All other states [2]	48,901	83,087

[1] Includes annunciators to the value of $25,320, for which number was not reported.
[2] Includes states as follows: California, Connecticut, Georgia, Illinois, Massachusetts, Michigan, Nebraska, New Jersey, Ohio, Oregon, and Texas.

The value of electric annunciators reported during the census year 1905 was $185,870, as compared with $224,885 five years earlier. As in so many other departments of electrical manufacture, the decrease of value is due rather to simplification and cheapening of the processes of manufacture than to a falling off in the demand. During the year no fewer than 93,140 annunciators were made. A very large number of the small annunciators were made for installation in modern dwellings, few houses of any pretensions being considered complete without an annunciator system connecting the sleeping apartments, servants' quarters, sitting rooms, dining room, etc. The bulk of the apparatus was produced in 5 states, in the order named—New York, Pennsylvania, Michigan, Illinois, and Massachusetts. The value in these 5 states aggregated $173,085, or 93.1 per cent of the total for the United States.

The principal development in this department has been in the substitution of lamp signal annunciators for the earlier needle type. In the new lamp annunciator, instead of needles or drops operated by magnets, the indications are furnished by small telephone switchboard incandescent lamps, which are connected to the various push buttons located at the point of call. In series with these lamps and buttons are lamp relays that are energized when the push button is pressed, and that keep the lamp illuminated until the call has been answered and the lamp has been cut off by means of a short-circuiting button or a number of buttons on the annunciator. Some of these new annunciators have a button to short-circuit the relays in this manner at the bottom of every column of lamps, and the arrangement gives satisfactory results. In connection with this system there is furnished on each annunciator either a single stroke bell or a buzzer, so that when the bell is used and the push button is actuated by the person making the call, one stroke is given on the bell, while when the buzzer is used the indication is given for just the length of time that the push button at the point of call remains in circuit under momentary pressure of the finger. These annunciators have the advantage of taking up less space than the needle type, and, as they are connected into the electric lighting system of the building, they avoid the necessity of a separate equipment of batteries for their operation.

A typical installation of this character is that which was furnished to a hotel in New York city. In each room is installed a special push button having a relay adjustment just behind it, so that when the button is pushed it is locked in by the relay and a lamp on the annunciator board is lighted at the same time that a single-stroke bell is operated. This button is kept locked until the lamp circuit is broken, whereupon it is released, making a slight click, notifying the guest that his call is receiving attention. Another feature of annunciator construction is that the lamps themselves are mounted in brass cylinders which are movable,

the motion being controlled by a spring. These are used to break the circuit, so that by pushing on the glass bull's-eye in front of the lamp the light is extinguished. There are two such annunciators on each floor, one being placed in the service room for service calls and the other in the hall or corridor for the maids' calls.

At another hotel in New York city an annunciator of the lamp type has been installed with 450 indicating lamps. The resetting mechanism to this annunciator is in the form of a button at the foot of each vertical column. This has given very satisfactory service in rapidly clearing out indications that have been noted and in lessening the cost of the individual resetting type, while eliminating the locking button in the guest's room. A further refinement of the system is that which furnishes means for ascertaining the room in which the chambermaid is temporarily engaged, and consists, in brief, of an electric lamp bulb which is carried about by the maid and is inserted by her into a socket as she enters the room, these sockets being provided along the corridor, one near every door. The insertion of the bulb into the socket lights it up and at the same time closes the circuit on a corresponding lamp on the annunciator in the main offices. Thus the location of the maid is indicated at each instant and at each room, both in the office and along the corridor, the process being repeated as the lamp is removed from the socket at one door and inserted at the next.

Table 19 shows the number and value of electric clocks and time mechanisms returned at the censuses of 1900 and 1905.

TABLE 19.—*Electric clocks and time mechanisms—number and value: 1905 and 1900.*

STATE.	Number.	Value.
United States, 1905	33,145	$373,926
1900	9,180	[1] 132,149
States, 1905:		
Illinois	14,195	89,222
Massachusetts	1,799	91,875
All other states [2]	17,151	192,829

[1] Includes clocks and time mechanisms to the value of $110, for which number was not reported.
[2] Includes states as follows: Colorado, Connecticut, Maryland, Missouri, Nebraska, New Jersey, New York, Ohio, and Pennsylvania.

The output of electric clocks and time mechanisms at the time of the census of 1905 was reported as having a value of $373,926, as compared with $132,149 in 1900. There was not only this marked increase in value but there was a corresponding increase in the number of pieces, 9,180 being reported in the earlier year and 33,145 in 1905. The production of this apparatus was carried on chiefly in the states of New York, Massachusetts, Illinois, and Connecticut, in the order named, these states producing 82.2 per cent of the total value for all states. There was also a fairly large output in Pennsylvania, Ohio, and Missouri.

The distribution of time by means of electric clocks is a relatively small industry without a widespread demand; but during recent years there has grown up a market for time mechanisms whose object it is to control the use of electric light and power. It may be desired, for example, to have electric lamps within a store burning for a period after the store has closed; or to keep the arc lamps burning outside a store or place of amusement up to a certain hour. For these and kindred purposes the time mechanism is inserted into the circuit and disconnects the lamps, motors, or consumption devices at the predetermined hour. In this manner the services of a lamp trimmer or attendant are dispensed with and the actual time of the use is known. There are several devices of this character. In a recent one, which may be taken as typical, the time switch has for its opening and closing devices a powerful spring-driven mechanism which tends at all times to revolve a disk carrying a crank which operates a loosely jointed connecting rod. This rod serves to open or close the switch with a snap-break movement. The motion of the driving disk is arrested by means of a spring-controlled lever, which is removed from contact with a lug on the disk by means of a hammer blow imparted by springs. The device is provided with two hammers, one for opening and one for closing the switch. The movement of each of these hammers is governed by disks driven at the rate of one revolution during each twenty-four hours. Each disk carries a pin so placed as to raise a steel pin on the corresponding hammer, thus allowing or causing the hammer to strike with a quick snap movement at the set hour for which the disk is adjusted. The two disks are independently adjustable, so that the switch can be set to open and to close at any time desired. This time mechanism is inclosed complete in an iron case ready for installation. It will be understood that there are various other time mechanisms of the same general character for registering the hour, such as watchmen's clocks, and the conveyance of information to a central point as to the increase or lessening of heat and pressure or the height of liquids in receptacles at certain hours.

Rheostats and resistances.—Table 20 shows the number and value of rheostats and resistances for 1905.

TABLE 20.—*Rheostats and resistances—number and value: 1905.*

STATE.	Number.	Value.
United States	75,695	$932,925
California	257	3,956
New York	21,205	230,015
All other states [1]	54,233	698,954

[1] Includes states as follows: Colorado, Connecticut, Illinois, Indiana, Iowa, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, Ohio, Pennsylvania, West Virginia, and Wisconsin.

In the Census report of 1900 all the kindred apparatus in the group of rheostats and resistances, electric

heating and cooking apparatus, electric welding appliances, etc., was massed together, and a total value of $1,186,878 was reported. In the present report it was felt that the increase in the production and use of apparatus for heating, cooking, and welding warranted an effort to separate that class from ordinary rheostats and resistances, and the result is that these data are now presented apart. The returns show a total for the United States of $932,925 as the value of 75,695 pieces of rheostats and resistances which were produced in 39 establishments. By far the largest proportion of this apparatus was produced in the state of Wisconsin, with New York in the second rank; these 2 states accounting in value for more than three-quarters of the total product. This apparatus is a necessary adjunct to the use of heavy current for lighting and power purposes, and large numbers are particularly called for in connection with the starting and regulation of electric motors, electric elevators, etc. Many of the smaller enameled resistances, however, have been introduced for use in connection with the most delicate electrical instruments and are now manufactured for employment as balance coils in telegraph service, and as shunting and ringing resistances in telephone circuits and relay signals. They are also to be found in use as resistances for locomotive electric headlights, for the control of phonographs, for small dental furnaces, etc.

The general principle adopted in the manufacture of all such apparatus is the embedding of fine wire offering high resistance to the passage of the current, in such insulating material as will also serve to take up and dissipate quickly the generated heat due to the interception of the flow of current by the high resistance wire. An idea of the difficulties encountered in such work is afforded by the requirement of the United States Navy Department that starting resistances, for use on shipboard, must be capable when called on of carrying 50 per cent overload of current for one minute and 100 per cent overload for twenty seconds. All resistances and all insulation used on them and their connecting wires must be noncombustible, and all connecting wires must be capable of carrying full-load current continuously without becoming dangerously hot. The method of mounting and insulating the resistances has to be such that the result of a burn-out would be practically the same in negligible effect as would occur with an entirely inclosed resistance. In general, the evil effect of heating must be minimized, both as regards the apparatus protected and in respect to any danger of conflagration from the concentration of so much heat at a given point. An extensive use of rheostats and resistances is made in connection with storage battery equipments for general purposes and more recently in connection with public garages, or plants for automobile charging.

Quite a distinct class of apparatus in this line is that employed on lighting circuits, especially those in theaters, where the increase or decrease in the volume of light, changes in colors, and many other effects are obtained by the use of "dimmer" resistances, which interrupt momentarily and partially the flow of current from the dynamos to the lamps or other illuminating devices. Very few theaters of any pretensions can now be found in the United States without electric lighting, and wherever this is installed "dimmers" will also be found in operation. Some idea of the extent to which they are employed may be formed from the fact that a theater in Chicago has a dimmer bank of 20 plates, with a total capacity sufficient for 810 lamps. A theater in Boston has 66 plates, with a total capacity sufficient for 2,670 lamps; one in New York has no fewer than 124 dimmers; and another, a dimmer board of 50 plates, with a total capacity sufficient for 2,400 lamps. One of the most interesting and capacious theater dimmers was that installed during the census year at Oakland, Cal., said to be the most compact apparatus of its kind, having a capacity sufficient to handle 3,000 lamps, that is, 36 dimmers, each caring for from 75 to 90 lamps, and taking up a space of only 5 feet 9 inches in width by 6 feet in height, and 18 inches in depth. This dimmer is worked independent of any switchboard and is made with as many as 60 to 250 steps, all parts being brought within reach of the hand and all wires and connections being within sight of the operator. Moreover, being mounted upon rollers, it can be moved around to any part of the stage by one man. The usual construction of theater dimmers, as indeed of resistances and rheostats in general, is to build them up in circular plate form, the wire of metallic alloy, which does not rust or fluctuate in its resistance, being embedded in the insulating material within the iron shell of the plate. When used with stationary electric motors, such resistances are placed on the side of the motor or machine or its base, or at some adjacent point, stands and boxes being manufactured for such purposes. In theater dimmers the resistances are usually mounted edgewise in banks, standing up somewhat as dishes on a dresser. The contact fingers move over the face of the plates or disks so as to cut in or out more or less of the resistance. A certain space is allowed between the disks for effective cooling, affording facilities also for insertion or removal of any single plate. These mechanisms are made to work singly or to operate with interlocking gears.

In some forms of apparatus for power purposes the starting and regulating rheostats for the motor are associated in one piece of apparatus. Such apparatus consists typically of a motor starter with a series of field buttons, controlled by a field resistance lever mounted on the same hub post as the starter lever and cooperating therewith. The motor is started and brought up to speed by moving the starter handle, which is also attached to the field regulator. They

thus move as one piece, and during the operation of starting the field resistance is short-circuited by an auxiliary contact mounted on the starter lever and by a curved sector located just below the armature contacts. When the two levers have been moved to the position in which all resistance is cut out of the armature circuits, a magnetic keeper on the starter lever is attracted by the retaining magnet and the lever is thus held in position. At this moment the auxiliary contact has left the curved sector, thus throwing the short-circuit off the field resistance. The field lever is now free to move over the field rheostat buttons on the face of the plate or disk, at the will of the operator, and can be left at any determined point, thus regulating the speed of the motor as desired. If the retaining magnet is deenergized, either by failure of voltage or by the operation of the overload—release devices which protect the apparatus and motor—the starter lever is released and returns to the original starting position, carrying with it the field rheostat lever. This compact and handy type of apparatus is used where it can be placed within reach of the machine attendant, and is usually mounted on the machine tool, whose driving motor it is intended to control. A further development of the disk rheostats has been their connection, on dynamo switchboards and dynamo testing boards, with a plunger or guide brought out to the front of the board so as to operate one or more of the plates and dispense with the former arrangement employing concentric shafts or gear wheels.

Heating apparatus.—Table 21 shows the number and value of electric heating, cooking, and welding apparatus reported in 1905.

TABLE 21.—*Electric heating, cooking, and welding apparatus—number and value: 1905.*

STATE.	Number.	Value.
United States	57,336	$395,827
Michigan	14,630	76,402
New York	5,043	160,960
All other states [1]	37,663	158,465

[1] Includes states as follows: California, Illinois, Maryland, Massachusetts, and Pennsylvania.

The production of apparatus in the United States for electric heating, cooking, and welding bids fair to become one of the largest departments in this field of industry. For while the present output is relatively small, the ramifications of the electric heating art are most numerous, and nearly every week sees a new application that had not previously been attempted or expected. According to the figures of the present census, no fewer than 15 establishments were engaged in the manufacture of these appliances, of which 57,336 were reported as having a total value of $395,827. This apparatus was produced almost entirely in 3 states, New York leading, followed closely by Massachusetts, while Michigan produced about half as much as either of them. Very few pieces of this apparatus were made elsewhere. The increased use of electric stoves, chafing dishes, grills, etc., flatirons and curling irons, soldering, sealing, and branding devices is largely due to the growing appreciation on the part of central station companies of the opportunities thus afforded them for the sale of energy in the daytime when the load upon the generating plant is lighter than at night. An idea of the extent to which such a development is going on is afforded by the fact that the report of the special committee on electric heating of the National Electric Light Association at Denver, in 1905, showed that out of 480 central station companies to which inquiries were addressed no fewer than 112 reported heating and cooking apparatus installed on their circuits. With average prices of electricity applied to apparatus here enumerated, it would appear that a small one-hole electric cooking stove, costing about $4, can be operated for half an hour for 4 cents. An electric flatiron heater costs 2 cents to operate for fifteen minutes. A water heater costs 5 cents an hour; an electric waffle iron, 5 cents for half an hour; a curling iron for the hair, $\frac{5}{10}$ cent for half an hour. This scale of cost does not compare favorably with gas or coal ranges on a basis of steady use; but the great advantages are that the electric current is immediately available, has peculiar advantages in the summer time, and is particularly applicable in places where fuel devices can not be permitted. Of late there has been a marked tendency in large hotels and in clubs toward the introduction of electric grills in the café or restaurant, where the heat given out by an open grill is objectionable, and where a large number of chops, steaks, and other viands are required simultaneously and with expedition. One of the largest of such appliances is capable of cooking over a hundred chops and steaks at the same time, each in its individual compartment. The piece to be cooked is inserted between the walls of a small compartment lined with electric resistances, which, being brought rapidly to a white heat, cook expeditiously and economically while preserving the juices and subjecting every part to the same temperature. The whole apparatus takes far less space than an open grill and is so inclosed that the heat is confined to do its work without radiating freely to the outer atmosphere; and to the casual eye the apparatus has rather the aspect of a refrigerator or a bank of letter boxes than a huge stove.

An effective illustration of the range of such apparatus in variety and utility is afforded by many an American home, and one may be instanced. All the apparatus thus employed is in regular manufacture, so that, provided electric energy is available, it can be installed anywhere. For example, the living room has

an electric radiator for medium warming purposes and an electric cigar lighter placed on the chimney mantel. A spacious veranda around the entire front of the house inclosed by glass is also heated when desired by a luminous electric radiator. In the sewing room is an electric pressing iron. In one of the sleeping rooms are an electric radiator and electric heating pads, which can be slipped between the bedclothes or placed upon the body, and an electric flatiron. The bathroom is fitted up with a small luminous radiator for warmth and a water heater for shaving. The laundry is equipped with electric flatirons, wash boilers, and emergency boiler heater. In a number of rooms the branch lighting circuits are tapped for the insertion of a wall receptacle, to which many of these devices can be temporarily attached, so that their use is not limited to any particular room or part of the house. In the kitchen no coal or gas is used, but everything is cooked by electricity. The cooking and baking outfit, which has been in use for over two years, consists of an electric oven, a cereal cooker, frying pans, vegetable boilers, small disk stoves, gridirons, and meat broilers. This outfit has been operated since its introduction, and for two consecutive Christmas dinners the electric oven has been employed with highly satisfactory results, including the cooking of a 14-pound turkey. The electric gridiron is 9 by 12 inches and is hot enough to fry cakes in two minutes. The cereal cooker is a combination device. In getting breakfast ready it is first used in heating water for the coffee and it is then used as a cereal cooker, and when the cereal is ready the interior dish is removed and eggs are boiled or steamed, using the boiling water then available. Later on potatoes are steamed, either for breakfast or for later meals. The frying pan and vegetable boiler are used frequently, particularly the pan, which is well heated in about a minute and is used principally in preparing bacon and eggs. For the washing of the dishes and utensils, particularly during the summer months, all the water is obtained by means of the emergency boiler heater, there being a receptacle near the sink for this purpose, and almost a momentary use of the current furnishes water adequate to the cleansing out of all the cooking utensils. The question naturally arises as to the cost involved in utilizing apparatus of this character, and it may be noted that twenty-four consecutive monthly bills for electricity during the two years show that the amounts range generally from $3.40 to $9.90, the average being $6.62 per month. This, however, includes the energy consumed for lighting; the bills for illumination previously being about $35 per year. Upon the installation of the heating and cooking apparatus, being largely a day load, the local public service corporation made a special rate of 5 cents per kilowatt hour. The price of apparatus may be arrived at from the statement that for a small family it would cost about $30 and for a large family about $60 for the special equipment, this comparing favorably with large size ranges or combination coal and gas stoves.

Perhaps the best exemplification of electric heating for industrial work is afforded by the equipment of the Government Printing Office in Washington. This office was equipped in 1904 with the largest electric heating system of the kind applied to such work, since when other devices have been added. The use of electric heat in the Office falls broadly into two groups or classes, one of these embracing and including matrix drying tables, wax stamping table, wax-melting kettles, case-warming cabinets, tool heaters, "sweating-on" machines, wax knives, and soldering-iron heaters. The other class, in the binding room, includes embossing and stamping heads, glue-heater equipments, glue-cooking pots, shaping machines for book covers, fitters, tool heaters, pamphlet-covering machines, sealing-wax molders, and other devices. The equipment of these electric heating appliances in the Office supplants steam and gas in all processes, except the stereotype melting pots, which are heated by gas.

The statistics of electric-welding apparatus are included in this section, but are not brought to account separately. Apparatus of this kind is in general use in the United States, and more particularly in connection with the welding of lengths of wire and cable in insulated wire factories and in bicycle and automobile shops. During the past ten years the employment of a number of complex metal parts in the construction of bicycles, and more lately of automobiles, has opened up a new field for the use of electric-welding apparatus. At the time of the Report on Electrical Manufactures in 1900 the rims of the steel supports for the rubber tires were the only parts then treated by this process. Since that time the extension of the art has made the application of electric welding embrace a much wider range, and it is stated that an ordinary automobile may now have as many as from four to twenty different parts that have been united in electric-welding apparatus. The process employed is usually that of bringing the two abutting pieces of the metal to a melting temperature secured by passing a definite and heavy current through them for a short period when pressed together, and thus closing the circuit. This welding is as effective, economical, and durable as can be secured in any other way, with a restriction of the heat required to the exact point of juncture. This method is still employed, or has been until a quite recent date, in the welding of street-car rails in situ, and elaborate sets of apparatus mounted in cars have been devised for such purposes.

Fuses and lightning arresters.—Table 22 presents statistics concerning fuses and lightning arresters reported in 1900 and 1905.

TABLE 22.—*Fuses and lightning arresters—number and value: 1905 and 1900.*

STATE.	Total value.	FUSES.		LIGHTNING ARRESTERS.	
		Number.	Value.	Number.	Value.
United States, 1905	$1,455,203	21,675,765	$868,079	1,324,523	$587,124

[1] Not reported separately.
[2] Included in "all other states."
[3] Includes states as follows: California, Connecticut, Georgia, Indiana, Missouri, Ohio, Oregon, Pennsylvania, and Texas.
[4] Includes states as follows: Colorado, Indiana, Iowa, Massachusetts, Missouri, Nebraska, New Jersey, New York, Ohio, Rhode Island, South Carolina, and Wisconsin.

The value of fuses and lightning arresters reported in 1905 was $1,455,203, showing a marked increase over the previous report, when it was returned as $595,497. This increase is due largely, if not wholly, to the general increase in electrical application and also to the recognition of the fact that it is a policy of economy to protect all classes of apparatus against lightning strokes, dangerous sneak currents, or sudden increases of the electrical energy flowing through the circuit. The lightning arrester equipment of a telephone exchange is an important and extensive part of the equipment, but it is probable that in many cases it has been included under the head of telephonic apparatus noted elsewhere, such arresters being made in certain types exclusively for telephonic work. There is, however, a very large field of application left, particularly in electric light, power, and traction, for which the insurance requirements are necessarily severe and exacting. The general type of fuse in the United States to-day is that which is known as "inclosed," the flash or action of the current discharge which opens the circuit taking place within a small chamber, like a cartridge shell. The tube is usually made of fiber, and contains a fusible strip surrounded by a filling material which combines with the material at the moment of "blowing" and thus absorbs or smothers the arc. These fuses are mounted on small stands or in boxes, according to their specific use, and are so arranged as to be readily or even automatically renewed or replaced after the protective action has occurred. In connection with street railway work these fuses are employed in fuse boxes and often in conjunction with circuit breakers, so that the heavier short circuits can be guarded against without damaging result to the apparatus or the persons in the vicinity.

Many fuses are employed of the metal strip type, fusing metal of a special composition being cut into strips, or wire, and held in the circuit between binding posts, so that any undue surplusage of electrical current will cause it to melt, and thus instantaneously open the circuit. These principles and appliances are employed in various ways, but, as noted, the particular form depends upon the use to which it is put and upon the volume of current against which the apparatus must be guarded. The national electrical code on the subject of the use of fuses makes the following provision, which will illustrate in a general way the application of these devices:

An approved cut-out (fuse) should be provided on service directly inside the building. Care should be taken to bring service in at point suitable for safe and convenient location of cut-out. An approved main switch should be provided as near as possible to where service enters, and be within easy reach of floor, so arranged that the entire equipment, including meter, can be disconnected when necessary. This switch should be protected by the main fuses. A separate branch cut-out should be provided for each 660 watts, i. e., the equivalent of about 11 or 12 sixteen candlepower lamps or 1 arc lamp. It is always good practice to have cut-outs assembled in groups, depending somewhat on the nature of the building, and placed in approved cabinets lined with slate, marble, or ½-inch asbestos.

Lightning arresters are of various construction. In one well-known type a magazine of fusible lightning arresters is provided so that they can become operative successively, one fuse providing for each lightning discharge. The arrester consists of two pieces of soft brass wire wrapped at their inner ends to form a discharge gap and inclosed hermetically in a small glass tube. One end of each fuse, or arrester, rests upon a common ground terminal, and the other is connected to the line terminal through a small carbon ball operated by gravity. In another type the arresters are composed of a series of special carbonized rings placed alternately in series with mica rings on an insulated tube, supported by two circular saw-toothed metal caps or brackets secured to the insulated base. The carbonized rings, by their composition and shape, afford an inner as well as an outer discharge circuit for the static charges, but will not permit arcs to form, nor a dynamo current to precede or follow. These arresters have no moving parts. Another form in general use is of the circuit breaker type, in which the air gap is fixed and the circuit is opened by the discharge in an inclosed chamber. This allows the use of a small air gap while providing an easy path to earth for the discharge. A resistance is used in series with the arrester coil to limit the current flow and in shunt to provide a noninductive path around the coil for the discharge. The parts are mounted on the base in such a manner as to avoid breakdown between parts of opposite potential on the surface. One type of lightning arrester manufactured in the United States has no air gap, its essential part being a specially constructed rod of very high ohmic but noninductive resistance, placed between the line and the ground, allowing a constant flow of current to escape through it to the ground, although to a very small degree. The inclosed circuit form of construction, while providing a path that will take care of a little static discharge and a heavier lightning discharge, as compared with an arrester with an air gap, has the advantage of being nonarcing and of having no moving

parts. The fact that the current is in constant flow through the arrester affords an additional assurance that the lightning will follow that path. Another type of lightning arrester which is installed in the power house, on poles carrying feeder lines, or on street railway cars, consists of two round terminals which form an adjustable spark gap, a noninductive resistance, and a magnetic blow-out coil, all inclosed in a porcelain box. The choke coils are interposed between the points where the arrester is connected to the circuit and the generator and motor to be protected. The spark gap terminals are mounted on the under side of the cover of the porcelain box, rendering them readily accessible for cleansing and inspection. For outdoor service the arrester is inclosed in a substantial wooden box. In electric railway work another form of lightning arrester in general use employs choke coils to flatten out the potential wave, while the arrester associated with it affords an easy path to the ground, and prevents the line current from following the discharge.

Included in the total for fuses of Table 22 is a large value, amounting to something over $300,000, reported by several establishments, representing electric fuses or exploders that are employed for setting off dynamite and other explosive charges, submarine mines, etc. The entire amount for 1 state represents fuses of this character. It will, of course, be understood that these fuses are of a somewhat different nature from those which are employed to open the circuit, rendering innocuous an abnormal flow of current or a lightning discharge. Electric fuses of the explosive or detonator character are operated either by means of direct spark from a small magneto-machine or by the incandescence of a thin wire placed in the circuit. This wire usually receives its current from a small battery upon which the circuit can be closed when it is desired to cause the explosion at the point in the circuit where the fuse and the explosive charge have been inserted. These two classes of fuses are known as high tension magneto, or low tension battery. Fulminate of mercury is employed frequently for such electric fuses, and it is a common practice to place a number of them in circuit at the same time, so that in mining and blasting operations several can be exploded simultaneously at different points. A fuller account of such apparatus was given in the chapter on electricity in mining contributed by the present writer to the special report, issued by the Bureau of the Census, on Mines and Quarries, 1902, pages 151 and 152.

Electric measuring instruments.—Table 23 shows the number and value of electric measuring instruments reported at the censuses of 1900 and 1905.

TABLE 23.—ELECTRIC MEASURING INSTRUMENTS—NUMBER AND VALUE: 1905 AND 1900.

[5] Includes states as follows: Connecticut, Georgia, Illinois, Indiana, Missouri, New Hampshire, New Jersey, Ohio, and Pennsylvania.

The production of electric measuring instruments for 1905 shows a large increase over 1900, the gain being from $1,842,135 to $5,004,763, or 171.7 per cent. This gratifying increase may be due in part to the fact that a number of instruments included in the previous report in "all other products" have been here separated more distinctly from the general output of concerns making more than one class of apparatus. The fact remains, however, that the past five years have seen in every department of electricity an adoption of methods for indicating the value and total quantity of electrical energy generated and distributed. No central station or isolated plant can be found without its measuring instruments. This is equally true of electric railway work, while in the field of telegraphy and telephony the employment of such instruments is considered vitally essential to the proper conduct of the business. In the field of electric light and power the earlier practice of selling energy or light at a flat rate is disappearing rapidly; even in small towns and villages it has become the practice to supply the consumer with a meter indicating his consumption of electricity, upon whose readings the bills are based.

At the census of 1900 no attempt was made to distinguish between the three main groups of electrical measuring instruments, namely, those for central stations, those for the consumers' circuits, and those intended for testing and scientific purposes. In the present returns figures have been obtained and are presented in the separate groups, thus giving an idea of the relative importance of these branches of industry. It would appear that 19 concerns were engaged in the production of central station apparatus, 14 in that for metering on consumption circuits, and 28 in

instruments for testing and scientific purposes. Of the central station apparatus, the value reported was $418,998 and the number of instruments was 22,090. By far the larger proportion of these in number and value was made in New Jersey, the states next in importance according to value being Pennsylvania and Massachusetts. To measure at the consumer's end of the line the output indicated by the central station instruments, there were made 336,929 meters, having a total value of $3,585,080, or an average value of about $10.50. The production of this apparatus was distributed widely and was participated in by several states, but owing to the small number of plants in each state the statistics can not be shown separately. Massachusetts, however, was the leading state, being followed by Pennsylvania, New Jersey, Indiana, and Illinois, in the order named, these 5 states accounting for over nine-tenths of the entire output. As a matter of fact, while these meters are being installed throughout the country, the larger cities are the chief centers of their use. New York, for example, with over 50,000 customers for central station supply, requires at least that number of meters. The central station indicating apparatus is practically uniform throughout the country, the leading types being voltmeters, ammeters, wattmeters, and watt-hour meters; but with regard to consumers' meters, although one or two types are predominant, greater variety prevails, depending somewhat upon the system adopted by the local company in charging for its service. A great many of the earlier meters were of the chemical type, but these have disappeared except where the expansion of a liquid by heat is employed to give an indication of the amount of current that has been required at different times and seasons, the charge being adjusted thereto on a sliding scale.

The testing and scientific apparatus is a very large group and includes numerous types and hundreds of varieties, employed not only in practical work, but in laboratories and in physical and scientific research. At one time practically the whole of this apparatus was imported from Europe, but, as will be noted, today there are more factories making it than are engaged in the production of meters of a more strictly commercial nature—an interesting and encouraging evidence of the growing skill of American manufacturers in a peculiarly fine and exacting industry. It is also worthy of note that instruments in all these three general groups are exported in increasing quantities and can be found in use throughout the world. During the year 1905, 58,067 instruments for testing and scientific purposes were made, having a value of $1,000,685. The chief center of their production was New Jersey, and through the commanding genius and inventive ability of one man that state is indeed one of the leaders in all three classes of products shown in Table 23. The other states giving special attention to this particular group of apparatus were Massachusetts, Pennsylvania, Connecticut, and New York.

The class of apparatus of most direct interest to the public is that which determines the amount of its consumption of energy for light and power. The watt-hour meter is one of the best known types of this and embodies a motor device of simple construction and of minute form. It consists essentially of two coarse wire coils placed in series with the circuit whose consumption is to be measured, and a fine wire coil connected in shunt around the circuit. The passage of electricity through the coarse wire coils creates the field of magnetic force which causes the fine wire coil to revolve. This shunt fine wire coil is supported in jeweled bearings, and its rate of rotation is proportional to the current in the circuit. A copper or aluminum disk is mounted on the same shaft as the shunt coil and rotates between the poles or arms of a permanent magnet. The current produced in the disk acts as a drag upon it, the drag being adjusted or calculated to give a speed proportional to the electrical energy supplied to the consumer. The number of revolutions is recorded by a clockwork escapement connected with small dials visible at the top of the meter case, and at any time the customer or the meter inspector can take a reading of the record of kilowatt hours that have been furnished.

A great deal of ingenuity in devising and in producing these small meters has been exercised, and the delicacy of operation involved has given employment to a large number of women, all the parts being of delicate construction, involving deftness of touch in their treatment and assembling. The relation of one industry to another is indicated by the large demand made in these instruments for jewels, such as Eastern sapphires, out of which the bearings are made, while the finest steel piano wire, about 0.03 inch in diameter, is employed for the pivots. A further development of such meters has been in the prepayment class, in which the insertion of a coin, closing the circuit, permits the use of a certain predetermined amount of energy. These meters, developed originally in Europe, are now being used and manufactured in this country also.

Circuit fittings.—Table 24 gives the statistics of production and value of circuit fittings at the census of 1905.

TABLE 24.—*Circuit fittings of all kinds—number and value: 1905.*

STATE.	Number.	Value.
United States	6,820,312	$3,525,446
Massachusetts	99,000	22,411
New York	1,035,220	2,493,242
Ohio	5,846	24,841
Pennsylvania	1,025,875	662,092
All other states[1]	4,654,371	322,860

[1] Includes states as follows: California, Colorado, Connecticut, Delaware, Illinois, Indiana, Michigan, Missouri, Nebraska, New Jersey, Oregon, and Virginia.

A classification which did not appear in the report of 1900 is that of "circuit fittings of all kinds." These were included in the last census under the general

heading of "all other products," but, as will be seen, they now constitute quite an important class, 6,820,312 items being returned, having a value of $3,525,446. The general and increasing utility of electricity for a variety of purposes too numerous to specify has necessitated the invention and manufacture of appliances to which the general name "circuit fittings" has been given, to designate that which is not part of the appliance itself, or part of the generating plant, or part of the distributing circuits and pole lines, but which at the same time is required in order to enable contractors and the public to install such apparatus advantageously. There are endless varieties of brackets, arms, reflectors, keys, connectors, insulating devices, stands, supports, receptacles, rosettes, bell switches, etc.; these multiply daily, each new branch of industry bringing with it novel requirements. There were in the United States 45 establishments engaged in this branch of work, chiefly in the states of New York, Pennsylvania, and Connecticut. By far the largest output was that of New York state, where 12 establishments reported a product of 1,035,220 pieces, having a value of $2,493,242. In Pennsylvania there were 9 establishments reporting 1,025,875 pieces, with a value of $662,092. The figures for Connecticut can not be shown separately.

All other products.—Table 25 shows, for 1900 and 1905, the value of all other electrical machinery, apparatus, and supplies not included in the preceding tables.

TABLE 25.—*All other products—value: 1905 and 1900.*

[5] Includes states as follows: Colorado, Connecticut, Georgia, Iowa, Louisiana, Maryland, Michigan, Minnesota, Missouri, Nebraska, New Jersey, Rhode Island, and Wisconsin.
[6] Includes states as follows: Colorado, Georgia, Iowa, Kansas, Kentucky, Louisiana, New Hampshire, North Carolina, Oregon, Texas, Virginia, and Washington.

45254—MFG 1905—PT 4—08——16

One of the largest groups included in this report is that shown in Table 25, for which a total of $26,634,963 was returned for 1905, as compared with $14,783,005 in the preceding Census report. This may seem a large aggregate, deserving of finer and more instructive subdivision, but as a matter of fact it is made up of a large number of individual items, few of which are relatively important. The three groups embraced in the 1905 total which were enumerated separately are "electric switches, signals, and attachments," valued at $1,451,337; "magneto ignition apparatus, including spark coils," valued at $678,077; and "electro-therapeutic apparatus," valued at $1,036,962. The electric switches and signals are in themselves auxiliary portions of what may be said to constitute telegraph systems for conveying intelligence as to the movements of trains, cars, elevators, and other transportation mechanisms. These systems are, as is well understood, elaborate combinations of electrical and mechanical parts.

The rapid development of the hydrocarbon automobile has created an enormous demand for ignition apparatus, the spark from which fires the explosive mixture of the air and gasoline vapor in the carburetter. The general principle is that when the piston is at the top of its stroke the mixture of vapor and air is ignited by the electrical discharge in it, and the violent explosion or expansion drives the piston down with great force, thus imparting motion to the reciprocating and revolving parts of the propulsive mechanism. Various methods of ignition are employed, based upon the electric principle. In what is known as the low-tension system, the car, while running, supplies its own electric sparking current from a small magneto, the moving part of which, in some forms, receives its oscillating action from a cam on the half-time shaft. These oscillations produce an intermittent current in the wire of the magneto-armature, which in turn causes a spark in the cylinder of the carburetter. The high-tension ignition system is that which employs primary or storage batteries, the current from which is sent through an induction coil, thereby inducing or creating a high frequency current. A commutating device, making and breaking contact, produces a high-tension spark within the combustion chamber at the right moment once during every four revolutions of the fly wheel, and the device is so arranged that the time of the spark can be varied by the chauffeur, who thus is able to cause the explosion to take place at an earlier and later point in the explosive stroke in the carburetter, this being known as advancing or retarding the spark. For the provision of a proper spark in the carburetter cylinder, the leading-in wires run to what is known as a sparking plug, which is a small metal device screwed into the top of the combustion chamber and containing a core of mica or porcelain through which the wire is led to a platinum point fixed in close proximity to another platinum point

which is connected directly with the metal of the automobile motor and car, so as to complete the circuit. The ignition spark jumps across the gap between these two platinum points. It is in these classes of apparatus that the magneto ignition devices and spark coils are employed, so that while the hydrocarbon automobile has proved a most serious rival with the electric vehicle it is to-day wholly dependent upon electricity for its ability to operate. No gasoline automobile of the modern type is complete that does not employ in the energization of its mechanism some of the devices included in this category.

The group of electro-therapeutic apparatus, valued at $1,036,962, was produced by no fewer than 66 establishments, chiefly in Illinois and New York. A great deal of this apparatus is still imported from Europe, chiefly from French and German sources, but in general the American medical practitioner has been more ready than those of the Old World to adopt electricity for surgical and curative purposes, and the advance in this country from both the technical and the industrial standpoint has been correspondingly rapid. A large number of medical men may be said to employ electricity solely in their work, and there are numerous clinics where electricity is the sole subject dealt with. Some of the equipments of leading men in this field are of the most elaborate and costly character, arranged in numerous separate compartments each fitted up with its specific or distinctive devices for X-ray work, electric light baths, charged liquid baths, the application of frictional or static electricity, and the treatment of disease where the direct internal or external application of current is deemed necessary. An idea of the importance now attached to this whole class of work may be formed from the fact that one of the sections of the International Electrical Congress held at St. Louis in 1904 was devoted to electro-therapeutics, while the transactions of the section constituted a large part of the report subsequently issued. Incidental to the work of this section was that in other branches of an allied character, such as the purification of water by electrical appliances and current, the study of microbes, treatment by phototherapy, and the effect of fluorescence in human organisms. The development of this whole field has indeed brought with it the requirement for a classification and nomenclature of the principles, phenomena, and apparatus that have become recognized during the past few years.

Laying aside the three classes which have just been referred to above, there remains a total of "all other products, not specified," amounting to $23,468,587. This was manufactured by no fewer than 376 establishments. This large number is in itself an evidence of the miscellaneous character of these factories and their products, and gives an average value of over $60,000 per establishment. It must not be understood that these 376 establishments were engaged exclusively in the production of this miscellaneous class of products, for the majority of them produced other specified electrical products, which have been included in their respective groups in the foregoing tables. The states contributing chiefly were New York, with 93 establishments, whose product was valued at $5,791,159; Massachusetts, 33, with product of $4,625,461; Ohio, 45, with product of $4,004,959; Pennsylvania, 37, with product of $3,851,506; New Jersey, 21, with product of $1,287,464; Illinois, 34, with product of $1,191,461; Connecticut, 15, with product of $569,003; and Indiana, 8, with product of $548,684. It will be observed from the table that these products were fairly well distributed through no fewer than 12 states in which the production exceeded $100,000, and that there were scattered establishments in others with a production aggregating several hundreds of thousands of dollars.

In many cases, especially of the larger companies, the schedules did not show the nature of the "all other products, not specified." Enough were specified, however, to give a fair idea of the character of products which make up the aggregate. They may be roughly grouped and enumerated as follows: Street railway supplies other than car equipment, to the value of $3,115,100, which includes such products as rail bonds and bonding tubes, line material, trolley-wire hangers, brackets and insulators, trolley gears and pinions, trolley wheels, contact alloys, etc. It is possible that one or two of these products are not strictly electrical in their nature, but they seem to be exclusively electrical in destination and use, and could hardly be included in any other industry. Another large class is that of machinery, tools, etc., to the value of $1,948,953. This group includes small electric engines or locomotives, elevators exclusive of motors, machinery for making incandescent lamps, magnetic ore separators, small electric pumps, electric disinfecting machines such as those which generate ozone by sparking, coal mining and cutting machinery, drills, tools, etc. A smaller group of somewhat similar nature consists of dynamo and motor parts and supplies, including armatures and field coils, pole pieces, etc., to a value of $283,224. In the same general group might be placed special controllers for dynamos, motors, and elevators to the value of $296,053, while it would not be an improper stretch of this wide classification also to include in it electrical novelties and toys, amount-

ing to the respectable value of $424,202. The mechanical toys of the present time are largely electrical in their nature, consisting of little dynamos and motors, electric railways, trolley cars, electric launches, portable lamps, and kindred devices. Insulating materials were specified to the value of $760,543, embracing materials of rubber, cloth, paper, compound, rubber substitute, etc.

A large variety of apparatus was reported as electrical household goods to the value of $213,039. This total is made up of such items as bells and push-button appliances, electric speaking tubes, electric door and mail box openers, electric filters, acousticons (for intensifying telephone transmission), and other miscellaneous appliances of the most heterogeneous character, and far too numerous to give even brief mention. A total of $203,659 was returned for electric signs. It is possible that some of the incandescent and miniature lamps are included in this total and to that extent involve duplication of the value reported under the heading of electric lamps. But the bulk of this item is made up of the framework of such signs or of the individual metal letters constituting them. This is a growing industry, but outside of the framework or background for the signs it consists largely in the assembling of other material from which the sign is built up, such as lamps, switches, insulators, wires, and cables. It is the almost universal practice to-day to employ carbon for the brushes making contact with the commutators of dynamos and motors, but other brushes are still in use to some extent, made of strip copper, wire gauze, and kindred material, and for these a value was returned of $84,283. There were also other miscellaneous products named, to the value of $610,902, embracing such items as electrical lining and attachments for wooden cabinets, safes, and vaults, for burglar protection, detailed parts for arc lamps, and jewels for electrical instrument purposes, etc.

Custom work and repairing.—Table 26 shows the amount reported for custom work and repairing at the censuses of 1900 and 1905.

TABLE 26.—*Amount received for custom work and repairing: 1905 and 1900.*

STATE.	Value.
United States, 1905	$2,798,922
1900	2,063,736
States, 1905:	
California	89,558
Colorado	8,350
Connecticut	12,301
Illinois	261,696
Indiana	65,211
Kentucky	8,450
Maryland	11,250
Massachusetts	116,737
Michigan	8,869
Minnesota	37,400
Missouri	100,941
New Jersey	146,619
New York	1,234,400
Ohio	335,251
Pennsylvania	204,634
Rhode Island	41,444
Wisconsin	58,970
All other states [1]	56,781

[1] Includes states as follows: Delaware, Georgia, Iowa, Louisiana, Maine, Nebraska, New Hampshire, North Carolina, Oregon, Tennessee, Texas, Virginia, and Washington.

The amount shown for 1905, $2,798,922, was reported by 331 establishments. These figures call for little comment, as it is a well understood fact that in the large majority of cases every factory has more or less work of this character, where the apparatus or parts of it are returned occasionally for repair or renewal, or where the production of individual pieces of apparatus is undertaken which does not fall within the ordinary line of manufacture. At one time this repair class of work constituted a large and profitable branch of employment for the limited number of electrical factories then in existence, but at the present all the larger electric lighting and power central stations, the electric traction systems, the telegraph systems, and the telephone exchanges have their own repair shops, and forces of men whose work is executed on the spot, not only because it is more economical to do this, but because the apparatus is required promptly in the work.

Table 27 is a detailed summary of the general statistics of the 784 establishments classified as electrical machinery, apparatus, and supplies, by states, for 1905.

METAL WORKING MACHINERY

METAL WORKING MACHINERY.

By FRED J. MILLER, Expert Special Agent.

The present report on metal working machinery embraces statistics relating to the manufacture of power operated machines for working metals, including also the parts and small tools necessary for the operation of the same. The term "metal working machinery" does not include machines or tools for use in the hand trades, such as plumbers' and tinsmiths' tools and watchmakers' lathes and tools, or rolling mill machinery, cranes, hoists, etc.

The statistics presented at the census of 1905 relate only to products, and no figures are given, as in the 1900 report, for capital, salaried employees, salaries, wage-earners, wages, miscellaneous expenses, and cost of materials used. The manufacture of metal working machinery is so closely connected with the manufacture of foundry and machine shop products that it was found impracticable in 1905 to separate the statistics concerning the manufacture of metal working machinery, except for products. Moreover, the statistics for 1905 are more comprehensive than those for 1900, it being the endeavor in the former to include returns for all establishments in which metal working machinery, including machine tools, is manufactured either as the principal or as a minor product; whereas the statistics for 1900 are confined to establishments in which metal working machinery alone was the principal product.

While the total production of metal working machinery reported at the census of 1905 shows an increase as compared with that for the census of 1900, it must be taken into consideration that the statistics include small machine tools, such as chucks, bits, dies, etc., and all working and interchangeable parts manufactured for metal working machines, which constitute a large proportion of the total product. These tools and parts were doubtless included to a greater extent in 1905 than in 1900, inasmuch as in 1905 there was a specific request made on the schedule calling for the value of the same manufactured during the census year; whereas no separate statistics are available for small tools for metal working machines manufactured in 1900, except under the general heading of "all other metal working machinery," and the large increase this item shows in 1905 in comparison with 1900 is due to some extent to a more complete canvass of the manufacture of this class of products.

In 1900 the statistics chronicled a period of great activity in the iron and steel industries and incidentally in the manufacture of metal working machinery. There was, however, a serious depression in business conditions in 1903, especially in all branches of the iron and steel industry, and although an improvement was noticeable toward the middle of 1904, the effect upon the returns for the manufacture of metal working machinery for that year was not marked.[1]

With these explanations the statistics of metal working machinery production in the United States are presented in 20 tables, which illustrate the industry as reported at the censuses of 1900 and 1905. Table 1 presents the value of products by selected states, with the proportion the value for each state forms of the total for the United States at the censuses of 1900 and 1905, and also the per cent of increase during the five-year period.

TABLE 1.—*Metal working machinery—value of products, by states, with per cent of total and per cent of increase: 1905 and 1900.*

STATE.	1905		1900		Per cent of increase.
	Value.	Per cent of total value.	Value.	Per cent of total value.	
United States...	$32,406,766	100.0	$24,737,904	100.0	31.0
Connecticut.....	3,965,742	12.2	3,162,003	12.8	25.4
Illinois.....	2,015,201	6.2	1,133,589	4.6	77.8
Massachusetts.....	4,819,687	14.9	2,844,319	11.5	69.4

[1] Decrease.
[2] Includes the value of products of establishments located in Arkansas, California, Colorado, Delaware, Georgia, Indiana, Iowa, Kansas, Kentucky, Maine, Maryland, Michigan, Minnesota, Missouri, Nebraska, New Hampshire, North Carolina, North Dakota, Oregon, Tennessee, Texas, Vermont, Washington, and Wisconsin.
[3] Includes the value of products of establishments located in California, Delaware, Georgia, Indiana, Iowa, Kentucky, Maine, Maryland, Michigan, Minnesota, Missouri, New Hampshire, North Carolina, Oregon, Vermont, Washington, and Wisconsin.

The greatest production of metal working machinery at the census of 1905 was reported for Ohio, which state was also first in 1900. The value of products for

[1] Statistics of the American Iron Trade for 1904.

Ohio formed over 25 per cent of the total value for the United States, and was greater than the combined value of New York, New Jersey, and Pennsylvania. In Ohio this industry is concentrated to a large degree in Cincinnati and Cleveland, these two cities together reporting 72.5 per cent of the total value of metal working machinery produced in the state in 1905, or 18.3 per cent of the total for the United States. Cincinnati was the leading city in the country in this industry at both censuses, and reported products valued at $3,200,889 in 1905, while Cleveland ranked second in the industry at the last census, with products valued at $2,740,618. Other cities in Ohio which are prominent in the manufacture are Hamilton, Toledo, Canton, Alliance, Springfield, and Warren, in the order named.

The state showing the greatest absolute increase in the manufacture of metal working machinery in 1905 was Massachusetts, the fourth state in rank in 1900, advancing to second place in 1905. The increase, however, was largely for "all other metal working machinery," which was more fully reported at the census of 1905 than at 1900. Worcester, the leading city in this industry in Massachusetts, reported a value of metal working machinery amounting to $1,079,772. There are also a number of large establishments in Worcester county, the products of which, if added to those for the city proper, would make the immediate locality one of the most important centers of this industry in the United States. New Bedford and Greenfield are also prominent in the manufacture of metal working machinery and tools.

Connecticut was the third state in the metal working machinery industry in both 1905 and 1900. The leading city in Connecticut was Hartford, the sixth city in the United States in this industry, and Waterbury, Bridgeport, New Haven, and Torrington also reported a large production. New York state has advanced from fifth place in 1900 to fourth in 1905, reporting an absolute increase in the value of metal working machinery manufactured, second only to that for Massachusetts. New York city, the third city in the United States in this industry, reported 61.3 per cent of the total production for the state, the bulk of this manufacture being in Brooklyn borough. The cities of Rochester and Buffalo also reported a large production of metal working machinery.

One of the noticeable features of the statistics is the fact that Pennsylvania, the second state in the manufacture of metal working machinery in 1900, ranked only fifth in 1905, a slight decrease being shown in the value of products reported for this state. The greater part of this decrease was in Philadelphia, which however, retained fourth rank among the cities of the United States in 1905, with products valued at $1,668,908.

Illinois reported a large increase in the manufacture of metal working machinery, advancing from eighth rank in 1900 to sixth in 1905, Chicago and Rockford reporting the principal production for the state. Rhode Island was seventh among the states in the metal working machinery industry in 1905. Of the total value for the state, 86.2 per cent was reported for Providence, the fifth city of the United States in this industry. New Jersey was the eighth state in the manufacture of metal working machinery in the United States, with Plainfield and Newark as the principal centers. Michigan, the ninth state in rank in 1905, shows a larger per cent of increase than any other state, the gain being due largely to the establishment of a large plant in Detroit in 1902. The production reported for Delaware, the tenth state in rank, was entirely for the city of Wilmington. The states of Wisconsin, Vermont, Indiana, New Hampshire, and Missouri ranked eleventh, twelfth, thirteenth, fourteenth, and fifteenth, respectively, in the production of metal working machinery in the United States as reported at the census of 1905.

Table 2 shows for each fiscal year between 1899 and 1905 the exports of iron and steel manufactures, and machinery of all kinds, including metal working machinery in comparison with the imports of iron and steel manufactures and machinery of all classes.

TABLE 2.—*Exports and imports of iron and steel manufactures and total machinery, and exports of metal working machinery: 1900 to 1904.*[1]

YEAR.	EXPORTS.			IMPORTS.	
	Iron and steel manufactures.	Machinery.		Iron and steel manufactures.	Machinery, all classes.
		Total, all classes.	Metal working machinery.		
1904.....	$111,948,586	$56,230,291	$3,716,709	$27,028,312	$3,184,968
1903.....	96,642,467	50,988,606	2,826,111	51,617,312	4,085,825

[1] "Commerce and Navigation of the United States," Bureau of Statistics, Department of Commerce and Labor.

As the foreign trade in iron and steel manufactures and machinery may be taken as an index of the conditions prevailing in the various branches of that industry, Table 2 shows clearly the fact that the manufacture of metal working machinery was depressed during the five-year period. In the table it is seen that the exports of iron and steel manufacture and machinery, including metal working machinery, decreased steadily year by year from 1900 to 1903, inclusive. In the same period the imports advanced largely, the value of iron and steel manufactures imported being over twice as large in 1903 as in 1900. On the other hand, in 1904, when business conditions in this country were improv-

ing in the iron and steel industry, there was a considerable increase in exports of iron and steel manufacture and machinery, including metal working machinery, and a marked decrease in imports, indicating that the production at home had increased and was supplying the domestic trade more completely than for several years previous. Nevertheless, the exports in 1904 show a considerable decrease as compared with the exports for 1900.

Table 3 shows the values reported for the several classes of metal working machinery, with the per cent the value for each forms of the total value; also, the per cent of increase during the five-year period.

TABLE 3.—*Metal working machinery—value of products by class of machines, with per cent each class is of the total and per cent of increase: 1905 and 1900.*

CLASS OF MACHINE.	1905		1900		Per cent of increase.
	Value.	Per cent of total.	Value.	Per cent of total.	
Total	$32,408,766	100.0	$24,737,904	100.0	31.0

Pneumatic hand machines	1,732,107	5.3	143,325	0.6	1,108.5
All other metal working machinery	9,090,189	28.1	2,726,901	11.0	233.4

[1] Decrease.

Table 3 shows a number of decreases in several important items, and if it were not for the marked increase in the value of "all other metal working machinery" the total value for 1905 would show only a small increase over 1900. As stated above, the increase in this class of product is due very largely to the greater comprehensiveness of the figures for 1905.

As shown in Table 3, lathes were the principal class of metal working machinery manufactured in both 1905 and 1900. The combined value of this class amounted to 18.3 per cent of the total value in 1905 and 29.1 per cent of the total in 1900. More than one-half of the total value reported for lathes was for engine lathes and over one-third for turret lathes, which includes the automatic and semiautomatic types, while a comparatively small proportion of the value was for hand lathes.

Table 4 shows the number and value of lathes manufactured by selected states for the censuses of 1900 and 1905.

TABLE 4.—*Production of lathes, including automatic, hand, engine, turret, and semiautomatic, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	14,486	$5,924,860	19,721	$7,207,069
Connecticut	1,326	700,785	2,108	1,030,314
Illinois	1,061	84,383	1,596	173,071
Massachusetts	4,690	856,946	4,534	1,348,168
New York	523	164,852	2,067	224,504
Ohio	4,639	2,571,883	6,121	2,624,064
Pennsylvania	122	129,112	293	358,759
Rhode Island	610	414,156	702	333,396
Vermont	319	321,765	367	284,411
Wisconsin	148	193,386	238	239,542
All other states	1,048	487,612	1,695	590,400

Over one-half of the total number of lathes manufactured in 1905 were engine lathes, 7,676 in all; 3,912 were hand lathes; and 2,898 turret lathes. The number of engine lathes manufactured in 1900 was 12,089; of hand lathes, 3,945; and of turret lathes, 3,687. It is thus seen that there was a decrease for each class, the greater part of the decrease being for engine lathes.

As seen in Table 4, Ohio was first in the manufacture of lathes, reporting 32 per cent of the total number manufactured at the census of 1905 and 43.4 per cent of the total value. This state also predominated in 1900, when the number reported formed 31 per cent of the total for the United States, and the value, 36.4 per cent of the total. Massachusetts was second in value of lathes manufactured in both 1900 and 1905, and although there was an increase in the number of such machines manufactured in that state, the value reported decreased slightly. The third state in rank in this production was Connecticut, where a considerable increase was shown in value reported of the lathes manufactured.

The class of metal working machinery second in value of products in 1905 was milling machines.

Table 5 shows, by selected states, the number and value of milling machines manufactured in 1900 and 1905.

TABLE 5.—*Production of milling machines, including all machines using a milling cutter, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	4,032	$2,476,626	4,119	$2,171,966
Connecticut	557	218,451	431	141,402
Massachusetts	745	376,222	437	317,518
New Jersey	71	115,722	155	167,510
New York	443	116,840	783	297,621
Ohio	856	529,157	1,060	438,725
Pennsylvania	50	110,282	79	110,605
Rhode Island	889	586,263	698	445,342
All other states	421	423,689	476	252,943

Table 5 shows that in spite of a slight decrease in the number of milling machines manufactured in 1905 as compared with 1900, there was an increase in the value of such machines as reported at the two censuses. Rhode Island, Ohio, Massachusetts, and Connecticut, in the order named, were the leading states, and each shows an increase in the value of this class of products.

The class of metal working machinery, which was third in value of products, was boring and drilling machines, including all machines using drills or boring bars.

Table 6 shows by states the number and value of this class of machinery manufactured in 1900 and 1905.

TABLE 6.—*Production of boring and drilling machinery, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	23,579	$2,369,712	22,890	$2,779,983
Connecticut	764	153,809	1,093	166,786
Illinois	14,281	334,614	2,936	145,083
Massachusetts	2,837	257,024	7,383	489,504
New Jersey	103	110,504	149	132,193
New York	653	50,112	1,792	83,308
Ohio	3,097	905,680	7,847	1,120,286
Pennsylvania	522	317,304	458	397,455
Rhode Island	130	65,518	128	75,135
All other states	1,192	175,147	1,104	170,233

The term "boring and drilling machinery" includes all metal working machines using drills or boring bars. As shown in Table 6, there was an increase in the number of boring and drilling machines for metal working manufactured in 1905 as compared with 1900, but the value of this class of products was somewhat less at the later census.

Ohio, which was the leading state at both censuses, shows a decrease both in number and value of boring and drilling machines, while Illinois, the second state in rank, shows a considerable increase, advancing from fifth place in 1900. Pennsylvania was third in both 1900 and 1905, while Massachusetts, which was second in 1900, dropped to fourth place in 1905.

Table 7 shows, by states, the number and value of stamping, flanging, and forming machines for plate and sheet metal, manufactured at the censuses of 1900 and 1905.

TABLE 7.—*Production of stamping, flanging, and forming machines for plate and sheet metal, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	8,235	$2,003,861	7,895	$1,180,960
Connecticut	711	149,703	645	216,728
Illinois	1,466	284,433	1,205	122,240
New Jersey	145	61,078	196	77,329
New York	4,487	1,057,508	2,362	541,226
Ohio	713	239,685	1,709	67,622
All other states	713	211,454	1,778	155,815

As shown in Table 7, more than one-half of the total value of stamping, flanging, and forming machines manufactured in 1905 was reported for New York, which state was first also in 1900. A considerable increase is shown also for Illinois, which state advanced to second place in 1905, superseding Connecticut, which held that rank in 1900. Ohio, which was prominent in the manufacture of other kinds of metal working machinery, ranked third in the value of stamping, flanging, and forming machines; while Connecticut, second in 1900, is now fourth in rank in this manufacture.

The most marked increase shown for any class of metal working machinery was for pneumatic hand machines, the manufacture of which was of little importance in 1900, but was of such prominence in 1905 as to be entitled to fifth rank in the industry.

Table 8 shows the number and value of this class of machines, as reported at the censuses of 1900 and 1905.

TABLE 8.—*Production of pneumatic hand machines: 1905 and 1900.*

	Census.	Number.	Value.
United States	1905	19,297	$1,732,107
	1900	6,751	143,325

The enormous advance in the manufacture of pneumatic hand machines is indicated in Table 8, the number of such machines manufactured having increased 12,546, or almost twofold, and the value, $1,588,782, or over elevenfold. The principal increase is shown for Michigan and Ohio, the statistics for which states are not presented separately, to avoid the possibility of disclosing individual operations. The increasing use of pneumatic hand machines is described fully in a later section of this report.

The type of metal working machinery next in rank in 1905, according to value of products reported, was planers, including plate edge planers.

Table 9 shows, by states, the number and value of planers manufactured at the last two censuses.

TABLE 9.—*Production of planers, including plate edge planers, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	1,100	$1,551,616	1,543	$1,808,955
Connecticut	41	25,253	60	52,782
Massachusetts	257	243,140	368	262,100
Ohio	385	466,836	646	691,362
Pennsylvania	63	252,746	188	248,812
All other states	354	563,641	281	553,899

The decrease shown in Table 9 in the manufacture of this class of metal working machinery is largely for Ohio, which was the principal state in this production in both 1900 and 1905. Pennsylvania and Massachu-

setts were second and third, respectively, in rank, the former state showing a slight increase in 1905 over the value reported in 1900.

The production of punching and shearing machines is shown, by states in Table 10, for 1900 and 1905.

TABLE 10.—*Production of punching and shearing machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	4,328	$1,425,510	5,269	$1,219,605
Connecticut	127	36,017	1,156	149,400
Illinois	602	142,526	124	68,771
Massachusetts	113	37,075	132	7,008
Michigan	106	9,153	45	18,000
New Jersey	577	69,677	432	82,242
New York	851	294,521	861	154,773
Ohio	330	312,405	395	319,690
Pennsylvania	106	79,267	82	44,499
Wisconsin	667	82,362	288	31,700
All other states	849	362,507	1,744	343,522

Ohio, New York, and Illinois, in the order named, were the three leading states in the value of this production in 1905; in 1900 the first two held the same positions, while Illinois ranked fifth. The first named shows a slight decrease in value of products, while the other two states show large increases.

Table 11 shows by states the number and value of grinding and polishing machines manufactured at the last two censuses.

TABLE 11.—*Production of grinding and polishing machinery, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	19,193	$1,310,903	10,014	$880,965
Connecticut	537	126,296	722	77,442
Illinois	109	5,584	1,963	92,464
Massachusetts	1,981	225,258	1,798	124,447
Michigan	983	82,963	301	11,568
New Jersey	232	13,325	50	6,601
New York	4,880	70,732	1,353	54,604
Ohio	1,273	114,840	295	17,126
Pennsylvania	362	267,213	797	143,468
Rhode Island	2,897	343,334	1,868	266,804
Wisconsin	948	32,532	219	48,410
All other states	4,991	28,826	648	38,031

The term "grinding and polishing" includes all metal working machines using an abrasive cutter. This branch of the metal working machinery industry increased largely at the census of 1905 compared with that of 1900, the increase in the number of grinding and polishing machines manufactured being 91.7 per cent and in the value 48.8 per cent. The leading state in the value of these products, both in 1900 and 1905, was Rhode Island, with Pennsylvania second.

Table 12 shows, by states, the number and value of boring and turning mills or vertical lathes for 1900 and 1905.

TABLE 12.—*Production of boring and turning mills or vertical lathes, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	611	$913,695	534	$1,123,314
New Jersey	15	24,805	54	177,089
Ohio	99	248,807	140	412,800
Pennsylvania	117	182,600	14	23,985
All other states	380	457,483	326	509,440

There was an increase in the number of boring and turning mills manufactured, but a decrease in value reported in 1905 as compared with 1900. Ohio was the principal state in the value of this production in 1905 as well as in 1900, despite a large decrease. Connecticut, the second state in rank, is not shown separately, as to do so would disclose individual operations. The production for Pennsylvania, the third state in rank in 1905, increased considerably. Delaware, the fourth state in this manufacture, is included with "all other states."

Table 13 shows the number and value of bolt, nut, and pipe threading and tapping machines for 1900 and 1905.

TABLE 13.—*Production of bolt, nut, and pipe threading and tapping machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	2,687	$899,197	2,088	$638,362
Connecticut	943	209,137	62	19,002
New York	203	128,030	259	128,709
Ohio	855	246,598	975	363,896
Pennsylvania	238	109,343	266	97,034
All other states	448	206,089	526	89,721

An increase is shown in the total number and value of bolt, nut, and pipe threading and tapping machines reported at the census of 1905, as compared with 1900; but in Ohio, the principal state in this manufacture, a decrease is noted. Connecticut, however, shows marked increases, which, with the increases reported for the other states, was sufficient to cause the totals for the United States to show a gain.

The production of slotters and shapers is shown, by states, in Table 14 for 1900 and 1905.

Table 5 shows that in spite of a slight decrease in the number of milling machines manufactured in 1905 as compared with 1900, there was an increase in the value of such machines as reported at the two censuses. Rhode Island, Ohio, Massachusetts, and Connecticut, in the order named, were the leading states, and each shows an increase in the value of this class of products.

The class of metal working machinery, which was third in value of products, was boring and drilling machines, including all machines using drills or boring bars.

Table 6 shows by states the number and value of this class of machinery manufactured in 1900 and 1905.

TABLE 6.—*Production of boring and drilling machinery, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	23,579	$2,369,712	22,890	$2,779,983
Connecticut	764	153,809	1,093	166,786
Illinois	14,281	334,614	2,936	145,083
Massachusetts	2,837	257,024	7,383	489,504
New Jersey	103	110,504	149	132,193
New York	653	50,112	1,792	83,308
Ohio	3,097	905,680	7,847	1,120,286
Pennsylvania	522	317,304	458	397,455
Rhode Island	130	65,518	128	75,135
All other states	1,192	175,147	1,104	170,233

The term "boring and drilling machinery" includes all metal working machines using drills or boring bars. As shown in Table 6, there was an increase in the number of boring and drilling machines for metal working manufactured in 1905 as compared with 1900, but the value of this class of products was somewhat less at the later census.

Ohio, which was the leading state at both censuses, shows a decrease both in number and value of boring and drilling machines, while Illinois, the second state in rank, shows a considerable increase, advancing from fifth place in 1900. Pennsylvania was third in both 1900 and 1905, while Massachusetts, which was second in 1900, dropped to fourth place in 1905.

Table 7 shows, by states, the number and value of stamping, flanging, and forming machines for plate and sheet metal, manufactured at the censuses of 1900 and 1905.

TABLE 7.—*Production of stamping, flanging, and forming machines for plate and sheet metal, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	8,235	$2,003,861	7,895	$1,180,960
Connecticut	711	149,703	645	216,728
Illinois	1,466	284,433	1,205	122,240
New Jersey	145	61,078	196	77,329
New York	4,487	1,057,508	2,362	541,226
Ohio	713	239,685	1,709	67,622
All other states	713	211,454	1,778	155,815

As shown in Table 7, more than one-half of the total value of stamping, flanging, and forming machines manufactured in 1905 was reported for New York, which state was first also in 1900. A considerable increase is shown also for Illinois, which state advanced to second place in 1905, superseding Connecticut, which held that rank in 1900. Ohio, which was prominent in the manufacture of other kinds of metal working machinery, ranked third in the value of stamping, flanging, and forming machines; while Connecticut, second in 1900, is now fourth in rank in this manufacture.

The most marked increase shown for any class of metal working machinery was for pneumatic hand machines, the manufacture of which was of little importance in 1900, but was of such prominence in 1905 as to be entitled to fifth rank in the industry.

Table 8 shows the number and value of this class of machines, as reported at the censuses of 1900 and 1905.

TABLE 8.—*Production of pneumatic hand machines: 1905 and 1900.*

	Census.	Number.	Value.
United States	1905	19,297	$1,732,107
	1900	6,751	143,325

The enormous advance in the manufacture of pneumatic hand machines is indicated in Table 8, the number of such machines manufactured having increased 12,546, or almost twofold, and the value, $1,588,782, or over elevenfold. The principal increase is shown for Michigan and Ohio, the statistics for which states are not presented separately, to avoid the possibility of disclosing individual operations. The increasing use of pneumatic hand machines is described fully in a later section of this report.

The type of metal working machinery next in rank in 1905, according to value of products reported, was planers, including plate edge planers.

Table 9 shows, by states, the number and value of planers manufactured at the last two censuses.

TABLE 9.—*Production of planers, including plate edge planers, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	1,100	$1,551,616	1,543	$1,808,955
Connecticut	41	25,253	60	52,782
Massachusetts	257	243,140	368	262,100
Ohio	385	466,836	646	691,362
Pennsylvania	63	252,746	188	248,812
All other states	354	563,641	281	553,899

The decrease shown in Table 9 in the manufacture of this class of metal working machinery is largely for Ohio, which was the principal state in this production in both 1900 and 1905. Pennsylvania and Massachu-

setts were second and third, respectively, in rank, the former state showing a slight increase in 1905 over the value reported in 1900.

The production of punching and shearing machines is shown, by states in Table 10, for 1900 and 1905.

TABLE 10.—*Production of punching and shearing machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	4,328	$1,425,510	5,269	$1,219,605
Connecticut	127	36,017	1,156	149,400
Illinois	602	142,526	134	68,771
Massachusetts	113	37,075	132	7,008
Michigan	106	9,153	45	18,000
New Jersey	577	69,677	432	82,242
New York	851	294,521	861	154,773
Ohio	330	312,405	395	319,690
Pennsylvania	106	79,267	82	44,499
Wisconsin	667	82,362	288	31,700
All other states	849	302,507	1,744	343,522

Ohio, New York, and Illinois, in the order named, were the three leading states in the value of this production in 1905; in 1900 the first two held the same positions, while Illinois ranked fifth. The first named shows a slight decrease in value of products, while the other two states show large increases.

Table 11 shows by states the number and value of grinding and polishing machines manufactured at the last two censuses.

TABLE 11.—*Production of grinding and polishing machinery, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	19,193	$1,310,903	10,014	$880,965
Connecticut	537	126,296	722	77,442
Illinois	109	5,584	1,963	92,464
Massachusetts	1,981	225,258	1,796	124,447
Michigan	983	82,963	301	11,568
New Jersey	232	13,325	50	6,601
New York	4,880	70,732	1,353	54,604
Ohio	1,273	114,840	295	17,126
Pennsylvania	362	267,213	797	143,468
Rhode Island	2,897	343,334	1,868	266,804
Wisconsin	948	32,532	219	48,410
All other states	4,991	28,826	648	38,031

The term "grinding and polishing" includes all metal working machines using an abrasive cutter. This branch of the metal working machinery industry increased largely at the census of 1905 compared with that of 1900, the increase in the number of grinding and polishing machines manufactured being 91.7 per cent and in the value 48.8 per cent. The leading state in the value of these products, both in 1900 and 1905, was Rhode Island, with Pennsylvania second.

Table 12 shows, by states, the number and value of boring and turning mills or vertical lathes for 1900 and 1905.

TABLE 12.—*Production of boring and turning mills or vertical lathes, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	611	$913,695	534	$1,123,314
New Jersey	15	24,805	54	177,089
Ohio	99	248,807	140	412,800
Pennsylvania	117	182,600	14	23,985
All other states	380	457,483	326	509,440

There was an increase in the number of boring and turning mills manufactured, but a decrease in value reported in 1905 as compared with 1900. Ohio was the principal state in the value of this production in 1905 as well as in 1900, despite a large decrease. Connecticut, the second state in rank, is not shown separately, as to do so would disclose individual operations. The production for Pennsylvania, the third state in rank in 1905, increased considerably. Delaware, the fourth state in this manufacture, is included with "all other states."

Table 13 shows the number and value of bolt, nut, and pipe threading and tapping machines for 1900 and 1905.

TABLE 13.—*Production of bolt, nut, and pipe threading and tapping machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	2,687	$899,197	2,088	$6[illegible]8,362
Connecticut	943	209,137	62	19,002
New York	203	128,030	259	128,709
Ohio	855	246,598	975	363,896
Pennsylvania	238	109,343	206	97,034
All other states	448	206,089	526	89,721

An increase is shown in the total number and value of bolt, nut, and pipe threading and tapping machines reported at the census of 1905, as compared with 1900; but in Ohio, the principal state in this manufacture, a decrease is noted. Connecticut, however, shows marked increases, which, with the increases reported for the other states, was sufficient to cause the totals for the United States to show a gain.

The production of slotters and shapers is shown, by states, in Table 14 for 1900 and 1905.

TABLE 14.—*Production of slotters and shapers, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	2,012	$845,860	3,076	$1,136,350
Connecticut	167	61,877	457	149,604
Massachusetts	124	33,575	238	79,050
Michigan	108	66,487	159	59,250
New York	64	13,518	334	78,165
Ohio	1,060	331,569	1,354	421,229
Pennsylvania	109	197,826	115	177,732
All other states	380	141,008	419	171,260

The production of slotters and shapers shows a decrease during the period reported, both in the number and the value of machines manufactured. The principal state in the value of these products at both censuses was Ohio, with Pennsylvania second in rank. This branch of the metal working machinery industry is concentrated largely in these two states, the value of their combined products representing 52.7 per cent of the total for these manufactures in 1900 and 62.6 per cent in 1905.

Table 15 shows the number and value of hammers—steam, power, and drop—for 1900 and 1905.

TABLE 15.—*Production of hammers—steam, power, and drop—by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	1,934	$832,698	857	$671,287
Connecticut	131	114,277	140	115,559
Illinois	208	53,000	24	45,446
Iowa	175	20,700	25	2,300
New Jersey	39	11,730	18	4,200
New York	378	238,642	233	109,968
Ohio	36	63,300	58	53,552
Pennsylvania	205	232,249	225	300,021
All other states	762	98,800	134	40,241

An increase is shown in Table 15, both in the number and value of hammers—steam, power, and drop—reported in 1905, as compared with 1900. The three leading states in this manufacture—New York, Pennsylvania, and Connecticut—together reported 70.3 per cent of the production in 1905 and 78.3 per cent in 1900. In 1905 New York ranked first, having advanced from third place in 1900, and showing an increase in the value of production of 117 per cent. Pennsylvania, first in rank in value of products in 1900, occupies second rank in 1905 with a considerably reduced production, and Connecticut, although holding second place as in 1900, shows a slightly diminished value of products in 1905.

The next class of metal working machines is bolt headers and other machines for forging hot metal with dies and with pressure. This manufacture is shown in Table 16 for the last two censuses.

TABLE 16.—*Production of forging machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	390	$437,097	821	$424,774
Ohio	195	305,397	230	290,300
All other states	195	131,700	591	134,474

The term "forging machines" includes bolt headers and all other machines for forging hot metal with dies and with pressure. A slight increase is noticeable in the value of this class of machinery manufactured at the census of 1905 as compared with 1900, but the number of machines is considerably less. This branch of the industry is concentrated to a large degree in Ohio, and although these machines are reported as manufactured in a number of other states the statistics can not be shown separately.

Riveting machines are considered as a class of metal working machinery, and the production as reported at the censuses of 1900 and 1905 is shown by states in Table 17.

TABLE 17.—*Production of riveting machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	645	$238,829	202	$139,295
Connecticut	257	100,657	76	20,728
New York	133	63,172	25	13,200
Ohio	36	9,525	6	300
Pennsylvania	148	42,980	81	102,370
All other states	71	22,495	14	2,697

The manufacture of riveting machines in the United States, though of small extent, increased materially during the five-year period reported. In 1905 Connecticut reported the principal production, superseding Pennsylvania, which was the leading state in 1900.

In Table 18 the number and value of bending and straightening rolls manufactured in 1900 and 1905 is shown by states.

TABLE 18.—*Production of bending and straightening rolls, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	174	$190,578	914	$202,230
Ohio	71	81,527	65	73,392
Pennsylvania	16	7,217	16	31,838
All other states	87	101,834	833	96,950

This type of metal working machinery shows a considerable decrease in number of machines reported and only a small decrease in the total value of the same in

1905 as compared with 1900. Ohio, the leading state in this manufacture, shows an increase in the value of production, while a decided decrease is shown for Pennsylvania.

The statistics for sawing machines, a class of metal working machinery which also shows a decrease in the five-year period from 1900 to 1905, are presented by states in Table 19.

TABLE 19.—*Production of sawing machines, by states: 1905 and 1900.*

STATE.	1905		1900	
	Number.	Value.	Number.	Value.
United States	2,806	$165,428	2,846	$222,563
Connecticut	49	1,830	277	11,947
Illinois	701	17,680	1,998	77,310
Ohio	101	23,648	16	2,203
Pennsylvania	209	77,220	193	99,953
All other states	1,746	45,050	362	31,050

The leading state in this manufacture, both in 1900 and 1905, was Pennsylvania; Ohio was second in importance in 1905, superseding Illinois, which was second in 1900.

There are numerous metal working machines not specially classified which are included under the general head of "all other metal working machinery," and this item is seen from Table 3 to form 28.1 per cent of the total for 1905. It may be that certain machines have inadvertently been included under this heading which by a strict ruling might properly belong under some of the itemized classifications, it being very difficult for certain manufacturers to accurately divide their product under the specific headings as required by the schedule. There is also included under this general head small tools, such as chucks, bits, and dies, which make up more than half of the total value reported; precision tools and machines; and duplicate parts, which are made to replace the wear on metal machinery already in use. This latter is a considerable item, inasmuch as most of the machinery in use to-day is standardized; that is, the parts are made largely to be interchangeable, and if a portion of the machine becomes worn or unserviceable it is not necessary to buy an entire new machine or to have a part made to order, as the manufacturer stands ready to furnish duplicate parts without delay.

Table 20 distributes the total value for "all other metal working machinery" among these several specified items for 1905, no separate report having been made for the same in 1900.

45254—MFG 1905—PT 4—08——17

TABLE 20.—*Production of "all other metal working machinery," by states: 1905.*

STATE.	Total.	Small tools for metal working machines.	Precision tools and machines.	All other metal working machines and duplicate parts.
United States	$9,090,189	$4,693,186	$995,430	$3,401,573
Connecticut	1,845,650	906,486	34,295	904,869
Illinois	651,609	254,672	21,727	375,210
Massachusetts	2,646,919	1,587,999	687,915	371,005
Michigan	221,703	106,833	.....	114,870
Missouri	115,391	59,096	.....	56,295
New York	1,036,397	405,091	5,256	626,050
Pennsylvania	392,793	275,024	3,075	114,694
Rhode Island	419,037	129,572	187,276	102,189
All other states	1,760,690	968,413	55,886	736,391

As seen in Table 20, Massachusetts was the principal state in the manufacture of small tools for metal working machines and also in precision tools and machines, with Connecticut second in rank in the former and Rhode Island in the latter manufacture. Connecticut leads in the manufacture of duplicate parts and all other metal working machines, with New York second and Illinois third, while Massachusetts is fourth in rank.

The total value of small tools for metal working machines manufactured in the United States in 1905 was $4,693,186, which was 14.5 per cent of the total for all classes of metal working machines. It was intended that only tools for use in power driven machinery were to be reported under this head, but it is possible that some hand tools have been included. However, as there may be some manufacture of this class of apparatus not reported, it is believed that the value presented is a fairly accurate report of this important branch of metal working machinery manufacture.

The value of duplicate parts and metal working machinery, not specified, as reported at the census of 1905, amounted to 10.5 per cent of the total for all classes of metal working machinery.

The following is a synopsis of the development of the metal working machinery industry from a technical standpoint:

DEVELOPMENT OF THE INDUSTRY.

Foreign use of American tools.—American made metal working machinery is found in almost every portion of the civilized world. Some of the best automobile factories of France, watch factories of Switzerland, small arms factories in Berlin, Germany and Liege, Belgium, and bicycle factories in Coventry, England,

are equipped with American built machinery. It is largely through the use of highly specialized machinery that American manufacturers are able to compete with the products of European shops. Whatever the cause underlying the superiority of American machinery, whether higher grade labor, the great incentive for workingmen to improve the machines they use, or because many mechanics have become manufacturers, or for all these reasons combined, the fact stands out that American tools are used extensively in foreign countries and that their effectiveness is recognized everywhere.

One of the greatest obstacles to the growth of the foreign trade of the United States in metal working machinery has been the difficulty of adjusting American tools to European shop methods, or of educating the European mechanic in the use of American tools. The influence of one upon the other is seen in the modification of American machinery to meet European ideas and the gradual change in European shop methods to meet the requirements of American machines and tools. An evidence of the close touch into which the machine and tool makers of the old and new worlds have been brought is found in the fact that an American technical journal, covering the field of machine tool construction, has 5,000 subscribers in Europe and is the medium for a constant exchange of ideas between the manufacturers and mechanicians of both hemispheres.

Specialization in manufacture.—One of the most striking features of the development of the metal working machinery industry is the specialization in manufacture that has taken place in recent years. This specialization has gone on to such an extent that there is not a single establishment in the United States in which a complete line of metal working machinery is constructed.

In this practice of confining an establishment to the manufacture of one class or a few distinct classes of machines, American builders have pursued a policy quite different from that of foreign builders, who usually are ready to undertake the manufacture of any machinery required by a customer. The tendency in the United States is toward a still greater specialization, and there is some indication of a disposition on the part of British and continental tool builders to adopt the same plan.

The progressiveness of American manufacturers is shown also in their readiness and ability to manufacture special machinery for use in a new machine building industry. This was true of the bicycle industry and is now true of the automobile industry.

High speed steel.—The invention of high speed steel has had a marked effect upon the development of the metal working machinery industry. The first of these steels was invented by Messrs. F. W. Taylor and Maunsel White, at Bethlehem, Pa., some time previous to the Paris Exposition of 1900. At that exposition they exhibited tools made of this steel, in use in a heavy and powerful lathe, taking heavy cuts at unheard of speeds—80, 90, or 100 feet per minute, instead of the 18 to 22 feet per minute that previously had been the maximum for heavy cuts in hard material. Such work attracted a great deal of attention, not only among builders of machinery, a considerable part of whose work consists in taking heavy cuts from imperfectly shaped castings or forgings, but also among steelmakers, a large number of whom, recognizing the importance of such steel, have undertaken to manufacture it.

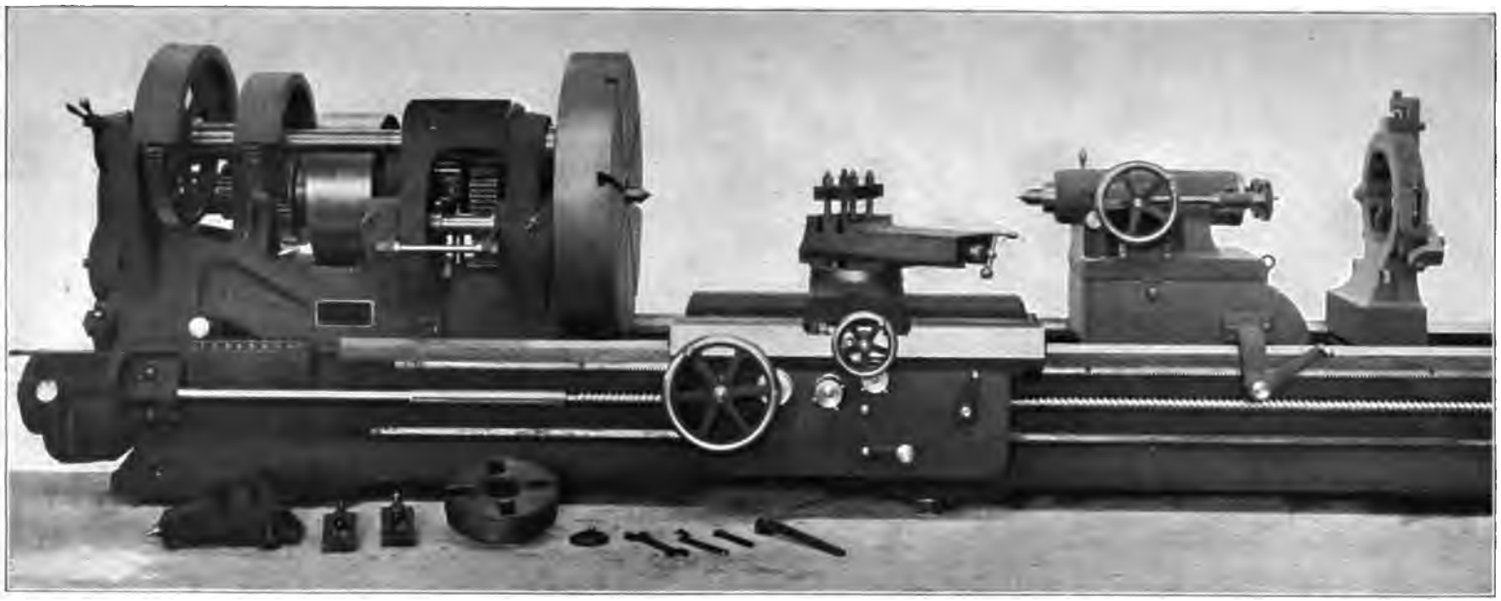
Although it is true that high speed steel is not stronger and will not take a heavier cut than the carbon steel previously used, if indeed so heavy, the fact that it will take a cut nearly as heavy at a very much higher speed has led to important modifications of certain metal working machines, especially lathes for heavy work.

One modification has been the redesigning of the driving mechanism of the lathe to make it capable of enduring for a reasonable time the stress of the greatly increased speeds. The belts and gears by means of which the power was commonly conveyed were so changed as to give the same torque, or driving force, with greatly increased speeds.

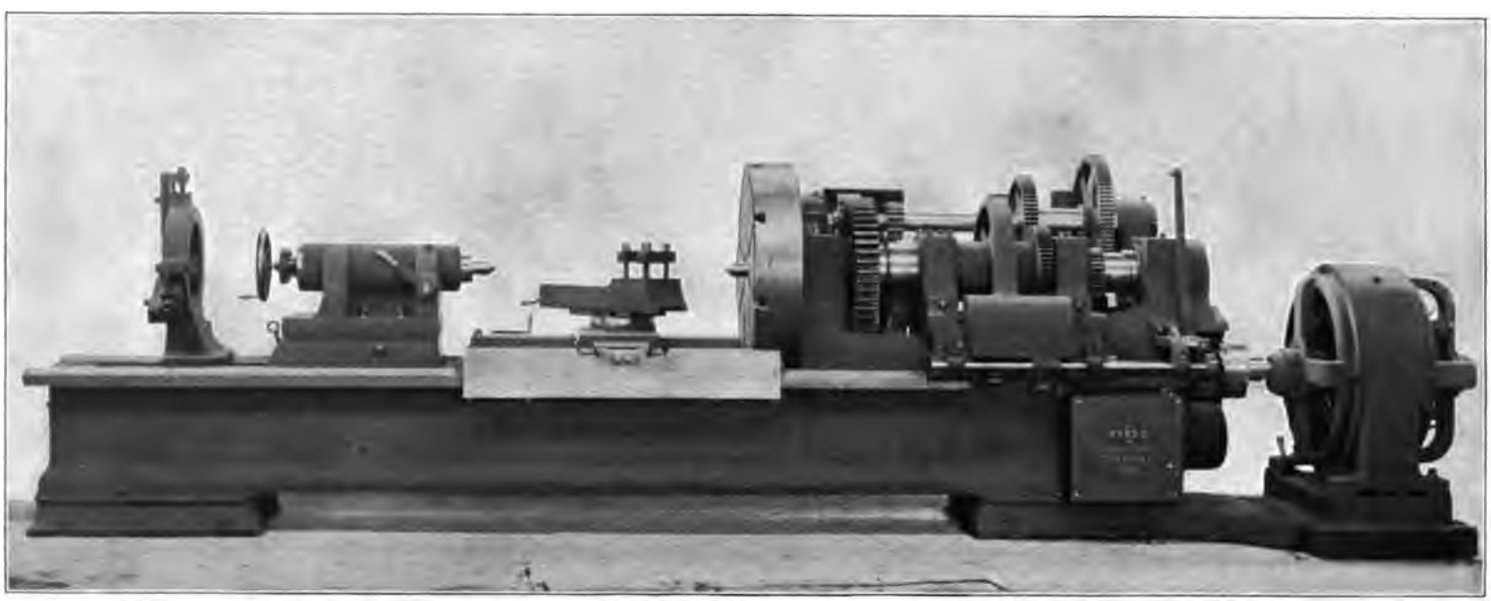
Another important modification has resulted from the fact that systematic tests made to show just how fast a heavy cut could be taken have led to a change of ideas as to what constitutes a heavy cut, and to a demand on the part of machine tool users for machines that will not only endure the higher speeds called for by the new steels but will also carry heavier cuts than were formerly thought to be practicable.

The use of high speed steel has resulted in a considerable reduction of the cost of certain kinds of work in machine construction, especially the removal of surplus metal from forgings and castings of iron and steel. This has led to some misunderstanding as to the total net effect of the use of high speed steel, the fact having often been overlooked that in the construction of many kinds of machinery, the chief item of expense is not the cost of taking such heavy cuts as may be required but the cost of the finishing processes which involve the taking of light cuts, careful gauging, grinding, hand scraping, and other operations that must be performed with care by skilled men. The cost of the finishing processes has been reduced but little by the use of high speed steels, and as in many cases they constitute the principal item of cost, high speed steel has affected the cost of producing the finer grades of machines much less than might have been expected.

Speed adjustment.—The use of high speed steels has led also to a much closer scrutiny of the speeds and feeds, or in other words, the rate of cutting and the thickness of the chip taken in cutting metals, and thus has



LATHE ARRANGED FOR DRIVING BY A CONSTANT-SPEED BELT.



REAR VIEW OF LATHE DRIVEN BY ELECTRIC MOTOR.

stimulated greatly the development of speed changing devices. Until a few years ago the stepped or so-called cone pulley, with one change by gearing, was practically the only device employed for altering the speed of a machine tool to adapt the speed to the requirements of the work in hand. Within the past five years, however, there has come the development and application of many new devices for this purpose, by means of which the operator, by merely shifting a lever, alters the speed without having to stop the machine to shift the driving belt from one to another position upon the pulleys, and without changing the speed of the driving belt itself. The belt is thus enabled, by its constant speed, to deliver energy to the machine at a uniform rate; a thing which it can not do when running upon cone pulleys, and which it is important that it should be able to do. An illustration of a lathe arranged for driving by a constant speed belt is shown on plate facing page 14.

Some of the geared heads developed by the improvement of speed changing devices are capable of imparting to the work not only a great total range of speeds, but the changes from a given rate to the next higher or the next lower are by much finer gradations; as a result there is a smaller loss of efficiency due to the fact that the available rate of speed nearest to that which would be exactly right for the work in hand is too high or too low. The ideal toward which designers are striving is an arrangement that, for any given piece of work within the capacity of the lathe or other tool, will give the exact speed for that work.

Electricity also has played an important part in the development of speed changing devices. Many machine tools are now driven by direct connected motors. In some instances the motors are incorporated as an integral part of the design, in others they appear rather as an attachment to the machine, which can with little alteration be driven either by a belt from shafting in the ordinary way or by a motor. The motors themselves are often arranged to run at varying speeds, though seldom with sufficient variation to cover the whole range required, the remaining speeds being obtained by the use of gears manipulated by shifting levers. By means of resistance boxes or of motors constructed so as to run at different speeds without the use of such boxes, together with gear devices, great ranges of speed, changing by small gradations, have been attained.

An illustration of a lathe driven by an electric motor is shown on plate facing page 14.

The front and rear views of a lathe having these modern driving arrangements are shown in the preceding illustrations; the lathe in each case being essentially the same but arranged for belt driving in one case and for motor drive in the other. Of the four uprights and bearings on the headstock, only the two outside or end ones support the spindle, the inner ones supporting only a sleeve to which the power is applied for driving, and which is bored through somewhat larger than the spindle so that there is no bearing of the one upon the other. The speed of the first motion shaft is constant and from it the varying speeds required for the work are obtained by the various gears shown, different combinations of which are obtained by means of clutches.

Portable tools.—The tendency to do things on an increasingly larger scale in all branches of industry has had a marked effect upon the machine tool industry, in that it has caused machine tools to be built larger, and has also given rise to the invention and adoption of smaller or portable tools.

Machine tools of large size are constructed to perform such work as is required at the time they are made. Since the cost of such tools is high, and their maintenance constitutes a large item of expense, the work they are called upon to do grows constantly larger. Nevertheless it has been found that certain classes of machine tools can not be built larger to advantage, since many castings which were formerly handled within the machines are now of such great size and weight as to make this method of machining them practically impossible.

To meet this condition a class of machine tools has been evolved which is designated as "portable;" these tools are portable in the sense that traveling cranes may pick them up and carry them where wanted. Such tools, instead of being constructed of such size and power as to enable them to take large castings within themselves, are designed only to hold, direct, and drive the cutting tools needed for the various operations to be performed, the pieces operated upon being held stationary upon the floor plates.

Attached or incorporated electric motors are employed usually for driving these portable tools. This enables them to be conveniently driven in any position in which it may be necessary to place them. It is now common to see a number of such portable tools working simultaneously upon one casting, so that boring, drilling, slotting, milling, key seating and other operations may all be done at one time, each independent of the others.

One of the latest and most interesting features of such work is the practice of setting in position both the work and the tools by means of a transit, much like that employed by civil engineers in surveying, but made with considerably greater refinement. This enables the attainment of the degree of accuracy required where allowable limits of error are usually stated in thousandths of an inch. These refinements have in turn raised the standard of accuracy so that in large electric generators and similar heavy work a degree of accuracy is now easily attained that would have been impracticable a few years ago.

Automatics.—A class of machines originally designed for making screws, but more recently employed also in making numerous small parts of machines and

other articles, and known to the trade as "automatics," has been developed considerably during the period covered by this report.

Only a few years ago automatic machines were made to handle stock only up to about 1 inch in diameter, and an "automatic" that could handle inch stock was looked upon as a large machine of its class. At first they were used almost exclusively for making the screws, hence the name "automatic screw machines." They are now made to handle steel bars up to 6 inches in diameter and are used for an almost endless variety of small parts. A more appropriate name for such machines, therefore, would be "automatic turret lathes," as their present function is not merely to make screws, but also to do lathe work.

An important addition to the automatic screw machines is the "magazine" attached to them, by means of which castings or small forgings are fed successively to the machines. At the Paris Exposition of 1900 an American tool builder exhibited a screw machine thus equipped which did all the machining operations upon the handwheel of a sewing machine, and required no attention whatever except to keep the magazine supplied with castings and the various cutting tools sharp and properly adjusted.

The variety of automatics known as the "multiple-spindle automatic" in particular has been developed greatly. In this machine there may be as many as five spindles, each holding and driving a separate bar of stock, to which the cutting tools are presented simultaneously for action. This means that a screw or other article requiring as many as five distinct operations to complete it may be made on this machine in the time required for performing the longest operation, because the tools used for performing the four shorter operations complete these before the operation requiring the longest time is completed. In some cases the apparently impossible task of reducing this time can be accomplished, as, for instance, where the time required for the longest operation is considerably greater than that required for any other, and the total number of operations to be performed is at least one less than the number of spindles in the machine. In such a case the principal operation is divided between two spindles, each performing one-half, so that the total time required for completing the piece is reduced to that of the next shorter operation, and thus the capacity of the machine is increased greatly.

A multiple-spindle machine is shown on the plate facing page 16, the four work-holding spindles being seen at the left and the tool-holding spindles in line with them at the right. In this machine the work-holding spindles may either rotate or remain stationary during a given operation and the tool-holding spindles may do the same. This fact is taken advantage of in arranging the various cutting speeds required. A speed may be that due to the rotation of the work-holding spindle alone, to that of the tool-holding spindle alone, or it may be the sum of or the difference between the two.

In threading work the operation of this machine differs from that of all others in that the work is held stationary during this process, and that all the chips are carried away by the oil being forced through the die-holding spindle, which is hollow, and through the die. When the thread is completed, no change takes place in the rotation of the die-holding spindle, but the work-holding spindle commences to rotate at higher speed in the same direction, and thus runs the die off without reversing the rotary motion.

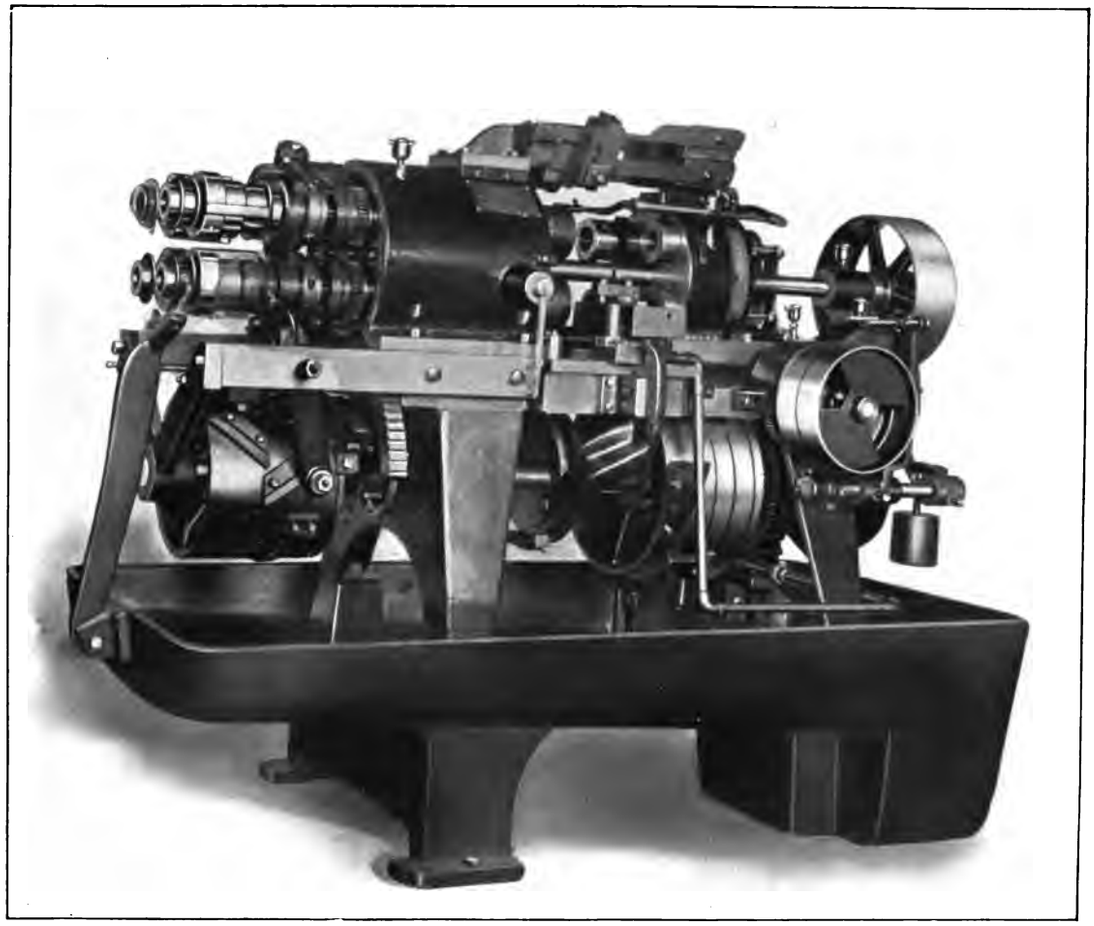
In another machine of the automatic class, which is still in the process of development, compressed air is used for moving the various parts of the machine in order to present the tools consecutively to the work and for the motions necessary for the cutting operations. The extreme lightness of air as compared with the mechanisms ordinarily employed for this purpose enables the motions usually designated as "idle motions" (to distinguish them from the motions used in actual cutting) to be made much more quickly than is otherwise possible, and thus the time consumed in the withdrawal of one tool and the presentation of another is reduced greatly.

Such improvements as these do not, however, materially reduce the labor cost of producing the work, because they do not affect the relatively small proportion of the work done by the operator. They reduce the cost only by giving a greater product with a given investment in machinery and tool equipment and within a given area of shop floor occupied. This reduction forms, however, in many cases a considerable proportion of the original total cost.

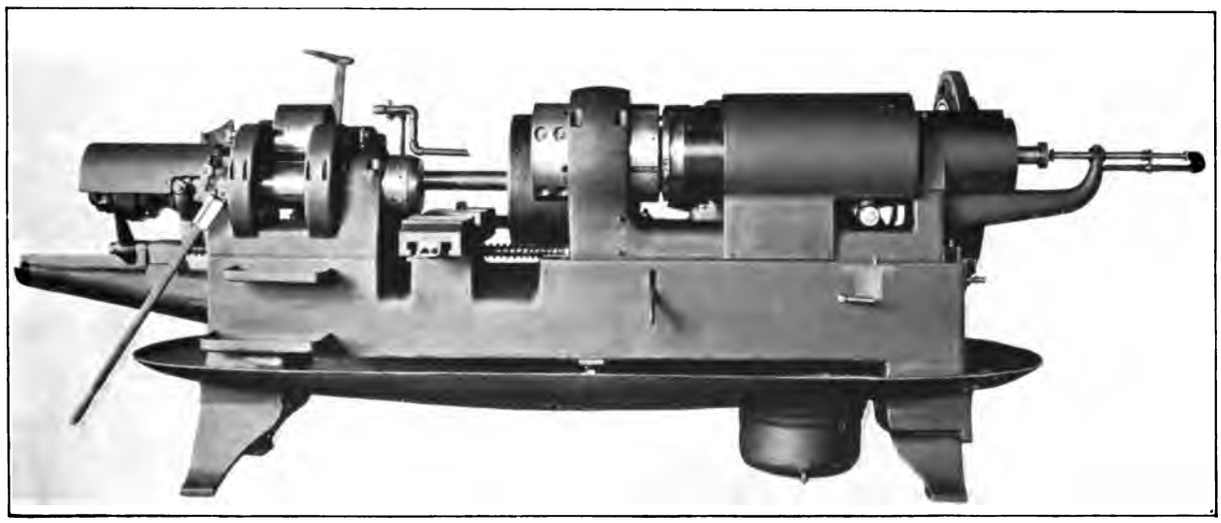
Compressed air seems likely to be used more extensively as machine tools are developed. The facility and rapidity with which it can be conveyed and its small mass makes it well adapted for use in metal working machinery. In fact, its extreme rapidity needs checking in some instances where uniformity of motion is required under varying resistance, and this check is applied by the use of a body of water or oil, which is forced by the air pressure through a restricted but usually adjustable opening and in turn acts upon the mechanism to be moved. The liquid, by resisting sudden changes in its rate of flow, regulates the speed of the motion.

The increasing use of automatic machine tools has led to the regular manufacture of automatic screw machines large enough to take bars of steel through their spindles up to 6 inches diameter and to make parts of machines from such bars. An illustration of such a machine is shown on the plate facing page 16.

The bars of stock, which may be the diameter named above and 10 feet in length and weighing about 1,000 pounds, pass through the spindle seen at the left, which is driven by incased gears that in turn are



MULTIPLE-SPINDLE AUTOMATIC SCREW MACHINE.



AUTOMATIC SCREW MACHINE FOR WORKING BARS 6 INCHES IN DIAMETER.

driven by pinions upon the shaft at the rear, on which the pulleys are to be seen. The turret in this type of machine has a horizontal axis, which is sufficiently offset from that of the spindle to bring the various cutting tools successively into line with the spindle for action. On the cross slide tools having a width up to 7 inches can be used for forming work, and the machine handles the 6-inch bars of steel entirely automatically with as much certainty and as little trouble as the smaller and more common sizes handle half-inch bars. The pipe connection at the extreme right is for forcing oil through the cutting tools, and the arrangement is such that only the tool which is in line with the spindle—i. e., in position for working—gets a supply of oil. The various levers seen are only for manipulating the machine at starting or in "setting up," its action being entirely automatic after it is started.

An automatic screw machine in which there is a partial application of compressed air for effecting the required movements is shown on the plate facing page 18.

The machine shown is equipped with a horizontal disk, which is placed above the turret and performs the function of a magazine. The machine is shown as arranged for drilling, chamfering, and tapping brass nuts for a 1-inch standard pipe thread, and all that is necessary is to place the blanks in the shallow recesses upon the surface of the disk. The machine presents them successively in position to be gripped by a vertically moving mechanism, which, taking one blank at a time, carries it down to a position in front of the chuck, from which it is placed within the chuck jaws. The chuck is then closed by air pressure, the various operations completed, and the finished nut ejected. The illustration gives a rear view of the machine, which shows the working parts better than a front view.

Some little adaptation of the turret mechanism usually has to be made for different pieces, and in the case of such a piece as a handwheel for a sewing machine the magazine is attached to the head stock instead of the turret, and the wheels move by gravity one after the other into position to be gripped by the device which carries them in front of the chuck. By some such means almost any casting or forging required in numbers sufficient to justify the outlay for tools and appliances can be finished without other manual labor than that required to place it in the magazine.

An "automatic" of a different type is shown on the plate facing page 18. This machine is intended for bars of stock up to seven-eighths of an inch in diameter and will feed this stock forward toward the tools any required distance up to 4 inches at a single movement. The machine is remarkable for its compactness, and its motions are made with great rapidity.

In general design it is a radical departure from the earlier machine shown in the special report made at the census of 1880. The turret has a horizontal instead of a vertical axis, and this axis lies at right angles to the axis of the spindle, thus bringing the turret nearer the operator for convenience in "setting up," and affording plenty of clear space for the tools.

The various motions are derived from cams which are placed upon two shafts running lengthwise to the bed. These shafts run comparatively fast, so that quick motions of the various tools are secured with very moderate angles of action upon the cams. The same illustration would answer for a number of similar machines of different sizes. Hardened steel parts are used freely to enable the machine to withstand the shocks incident to great rapidity of motion, and its freedom from noise is remarkable.

New grinding process.—The process of grinding, which was formerly applied only to the work of finishing true and to size such parts of machines and tools as were made of steel so hardened as to make cutting tools unavailable, has of recent years been developed and applied much more widely than before. It is now used for finishing to size many cylindrical parts of machines formerly finished by the much less certain and precise method of turning in a lathe.

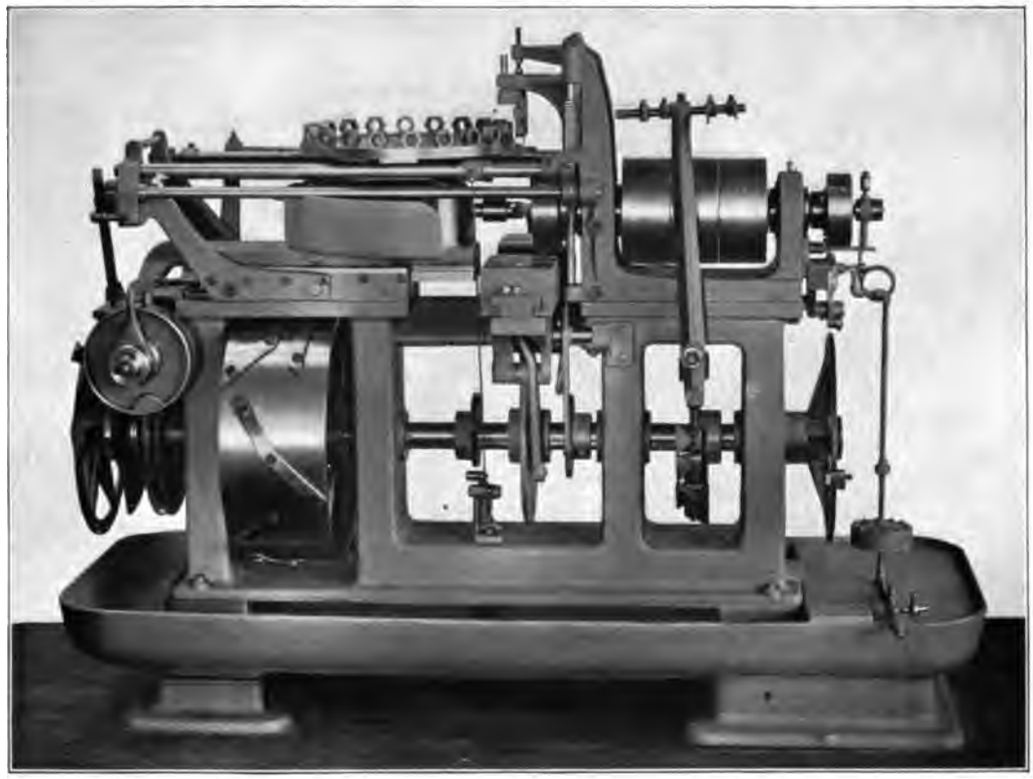
Marvelous results in grinding have been obtained by applying great power to driving a relatively large and heavy abrasive wheel which at every turn is made to sweep over the work the full width of the wheel. For instance, in refinishing locomotive piston rods that have become badly worn or scored, a special grinding machine of this kind has been invented which does the work more quickly and with much greater precision than is possible by the older methods. In finishing automobile crank shafts, work which is tedious by ordinary methods, this process of grinding has proven remarkably efficient.

Interchangeable tools.—As a result of the specialization in machine tool manufacturing, many American tools are now made wholly or in part upon the interchangeable plan. The extent to which this plan is used in a given shop depends mainly upon the number of identical machines to be built. Most machine tool establishments have long made certain parts of their machines upon the interchangeable system. Screws, bolts, change gears, and other things, component parts of engine lathes and used in numbers much larger than the number of lathes built, have usually been made in large quantities "for stock." Such parts can be made upon the interchangeable plan with sufficient accuracy, by means of special tools and gauges which cost little, if any, more than such tools as would be required to make similar parts without regard to interchangeability. For other parts of the lathe,

however, the tool equipment required for interchangeable manufacture is more elaborate. Such tools have been made and used only as the number of identical lathes to be manufactured in a given shop has increased to a point justifying the expense.

This fact has led to a great difference in practice between different shops; those building many lathes having carried the principle of interchangeable manufacture very far, while others have applied it to only a limited extent. Naturally also the size of the lathes built in a shop has considerable influence, because for large lathes, built in small numbers and for which the tools and fixtures are much more costly, a point is soon reached at which the proportionate cost for tools which must be charged to each lathe becomes prohibitive.

The development of the industry which has been going on has, however, led to an increasing application of the principle of interchangeable manufacture to the production of metal working machinery, and this is one of the most prominent, important, and interesting features of the business as now carried on. Even some of the larger machines which, a few years ago were built one at a time and only upon orders, are now manufactured in considerable numbers by the aid of special tools and fixtures and with many if not all of their parts interchangeable.



AUTOMATIC SCREW MACHINE WITH MAGAZINE ATTACHMENT.

AUTOMATIC SCREW MACHINE.

MUSICAL INSTRUMENTS, ATTACHMENTS, AND MATERIALS

MUSICAL INSTRUMENTS, ATTACHMENTS, AND MATERIALS.

By WILLIAM F. WORCESTER.

The census of 1860 was the first to accord special treatment to the manufacture of musical instruments. Subsequently no special report upon the industry was prepared until the census of 1900, when a report entitled "Musical Instruments and Materials" was published. From the census of 1880 to that of 1900, inclusive, the establishments manufacturing this class of products were classified, according to the product of principal value, as follows: "Musical instruments and materials, not specified;" "musical instruments, organs and materials;" and "musical instruments, pianos, and materials."

The manufacture of materials for organs and pianos conducted apart from the establishments producing the finished articles is now a well defined branch of the industry, and accordingly, at the census of 1905 establishments manufacturing materials for organ and piano makers were classified as "musical instruments, organ and piano materials," instead of being merged with the manufacture of organs and pianos, as indicated above. The classifications "musical instruments, organs," and "musical instruments, pianos," of the census of 1905, therefore, are not comparable with the classifications of previous censuses covering the same products, since the latter include also the production of piano and organ materials.

THE COMBINED INDUSTRY.

In Table 1 is presented a combined comparative summary showing the progress of the industry from a statistical standpoint since 1860.

TABLE 1.—MUSICAL INSTRUMENTS, ATTACHMENTS, AND MATERIALS—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1860 TO 1905.

	CENSUS.						PER CENT OF INCREASE.				
	1905[1]	1900[2]	1890	1880	1870	1860	1900 to 1905	1890 to 1900	1880 to 1890	1870 to 1880	1860 to 1870
Number of establishments	625	619	674	429	337	223	1.0	[3]8.2	57.1	27.3	51.1
Capital	$72,225,379	$47,706,582	$29,650,489	$14,446,765	$9,554,761	$4,431,900	51.4	60.9	105.2	51.2	115.6

Children under 16 years	584	535	83	250	98	(5)	9.2	544.6	[3]66.8	155.1	.....
Wages	$119,152	$107,520	$14,997	(5)	(5)	(5)	10.8	616.9	.....	.....	.....
Miscellaneous expenses	$7,564,994	$3,783,714	$2,394,316	(6)	(6)	(6)	99.9	58.0	.....	.....	.....
Cost of materials used	$29,116,566	$18,576,022	$14,436,163	$8,361,227	$4,834,552	$2,144,298	56.7	28.7	72.7	73.0	125.5
Value of products	$69,574,340	$44,418,978	$36,868,169	$19,254,739	$13,905,908	$6,548,432	56.6	20.5	91.5	38.5	112.4

[1] Exclusive of the statistics of 3 establishments engaged primarily in the manufacture of products other than musical instruments, attachments, and materials. These establishments made musical instruments to the value of $69,114.
[2] The totals do not agree with those published in the general tables at the Twelfth Census because of a reclassification.
[3] Decrease.
[4] Includes proprietors and firm members, with their salaries; number only reported in 1900 and 1905, but not included in this table.
[5] Not reported separately.
[6] Not reported.

It is apparent from the table that as early as 1860 the industry had assumed proportions of some importance. At that time there were 223 establishments which produced musical instruments to the value of $6,548,432. Since that date the figures in each census have exceeded those of preceding decades for every item, with the exception of the number of establishments and the number of children employed. At the census of 1900 the number of establishments decreased for the first time. This decrease is in

line with the concentration movement which has characterized so many of the industries in the United States during the past fifteen years. As a result of the movement in this industry, the table shows that since 1890 the operations of the average establishment have practically doubled.

A notable feature of the table is the increase in the industry since 1900. The absolute increase of $25,155,362 in the value of products for the five years is greater by far than the absolute increase for any of the ten-year periods shown, over three times as large as that of the decade preceding, and about equal to that of the twenty years from 1880 to 1900.

In Table 2 the aggregate for the different statistical items at the census of 1905 are distributed by industries.

TABLE 2.—MUSICAL INSTRUMENTS, ATTACHMENTS, AND MATERIALS—SUMMARY, BY INDUSTRIES, WITH PER CENT OF TOTAL: 1905.

	Total.	Pianos.	Per cent of total.	Organs.	Per cent of total.	Piano and organ materials.	Per cent of total.	Instruments and materials not specified.	Per cent of total.
Number of establishments	625	249	39.9	94	15.0	101	16.1	181	29.0
Capital	$72,225,379	$49,649,135	68.7	$7,203,878	10.0	$11,628,897	16.1	$3,743,469	5.2
Salaried officials, clerks, etc., number	2,947	2,068	70.2	323	11.0	331	11.2	225	7.6
Salaries	$3,979,696	$2,846,685	71.5	$372,362	9.4	$508,883	12.8	$251,766	6.3
Wage-earners, average number	35,220	21,002	59.6	3,623	10.3	8,456	24.0	2,139	6.1
Wages	$19,689,146	$12,170,251	61.8	$2,034,559	10.3	$4,322,268	22.0	$1,162,068	5.9
Miscellaneous expenses	$7,564,994	$5,532,420	73.1	$818,276	10.8	$787,475	10.4	$426,823	5.7
Cost of materials used	$29,116,566	$19,587,770	67.3	$2,068,638	7.1	$6,330,219	21.7	$1,129,939	3.9
Value of products	$69,574,340	$46,922,471	67.4	$6,041,844	8.7	$13,128,315	18.9	$3,481,710	5.0

The statistics reveal at a glance the overwhelming importance of the piano industry when compared with the others which compose the combined industry. To the manufacture of pianos, piano players, and attachments were assignable 68.7 per cent of the aggregate capital and 67.4 per cent of the aggregate value of products of the combined industries at the census of 1905. Next in importance was the manufacture of piano and organ materials, which in value of products considerably exceeded the value of the combined output of the two remaining industries. In connection with this branch it should be noted here that, theoretically at least, the entire value of product of the industry is duplicated in the combined aggregate. The products of the establishments comprising the classification must pass through the organ or piano factory, where they are incorporated with other materials to form the final products, and thus their value is included twice in the aggregate value for the four industries. Necessarily, then, as the specialization in the manufacture of pianos and organs increases and the final producers of the instruments become more and more assemblers of parts rather than manufacturers, the duplication in the products of the combined industries will become greater. Since the manufacture of piano and organ parts has not been segregated previous to the present census, it is impossible to draw any inference from the table concerning the growth of this tendency toward specialization in the manufacture of these instruments. Significant and interesting conclusions concerning the growth may be drawn from subsequent censuses, however, in case the values returned for the products of the classification "musical instruments, piano and organ materials" constitute increasing proportions of the values reported for the products of the combined industry.

Many establishments engaged primarily in the manufacture of pianos produce also some organs, while others, whose principal products are organs, manufacture a limited number of pianos. Since the establishments are classified according to the product of greatest value, it is impossible to avoid some intermingling of products. Thus the value of products for the classification "musical instruments, pianos," will include the value of some organs, and the value of products of "musical instruments, organs," will include the value of the pianos produced as products of secondary value by the establishment in this classification.

Table 3 indicates the extent of the intermingling of products at the census of 1905, showing in detail the kind, number, and value of the pianos and organs produced by the establishments in the two industries.

TABLE 3.—*Musical instruments, pianos and organs—products of each industry, by kind, quantity, and value: 1905.*

KIND.	Total.	Pianos.	Per cent of total.	Organs.	Per cent of total.
Aggregate value	$52,964,315	$46,922,471	88.6	$6,041,844	11.4
Pianos, total value	$43,502,055	$42,874,395	98.6	$627,660	1.4
Upright—					
Number	251,957	250,204	99.3	1,753	0.7
Value	$37,397,674	$37,116,668	99.2	$281,006	0.8
Grand—					
Number	7,372	7,372	100.0	.....	.....
Value	$3,661,423	$3,661,423	100.0	.....	.....
Other varieties, including street and self-playing, players, and attachments	$2,442,958	$2,096,304	85.8	$346,654	14.2
Organs, total value	$6,625,319	$1,668,493	25.2	$4,956,826	74.8
Reed—					
Number	113,065	43,028	38.1	70,037	61.9
Value	$4,162,053	$1,489,802	35.8	$2,672,251	64.2
Pipe—					
Number	901	75	8.3	826	91.7
Value	$1,989,979	$124,736	6.3	$1,865,243	93.7
Other varieties, including street and self-playing	$473,287	$53,955	11.4	$419,332	88.6
All other products	$2,836,941	$2,379,583	83.9	$457,358	16.1

The table shows that while only 1.4 per cent of the total value of the output of pianos of all kinds was reported by establishments primarily engaged in the manufacture of organs, practically a quarter, 25.2 per cent, of the value of all the organs produced during the census year resulted from the operations of piano factories. The value of organs built in piano factories, however, formed only 3.6 per cent of the aggregate value of the products of these factories. It is in the manufacture of reed organs that the encroachment of the piano factories upon the field of organ manufacturers is most noticeable, 43,028 of this variety of organs, or 38.1 per cent of the total production, having been produced during the census year by piano manufacturers.

In Table 4 the aggregate of the combined industries in 11 selected states that were large producers of musical instruments at the census of 1905 is shown for the censuses from 1880 to 1905. The remaining states which produced musical instruments at each census period are combined to form "all other states."

TABLE 4.—MUSICAL INSTRUMENTS, ATTACHMENTS, AND MATERIALS—COMPARATIVE SUMMARY, BY SELECTED STATES: 1880 TO 1905.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.

[1] Includes establishments distributed as follows: Colorado, 3; Delaware, 1; Georgia, 1; Iowa, 3; Kansas, 2; Kentucky, 7; Louisiana, 2; Maine, 2; Maryland, 11; Minnesota, 9; Nebraska, 2; New Hampshire, 4; Oregon, 1; Rhode Island, 1; Vermont, 3; Virginia, 1; Washington, 3; West Virginia, 1; Wisconsin, 6.

[2] Includes establishments distributed as follows: Colorado, 4; Iowa, 7; Kentucky, 8; Louisiana, 1; Maine, 1; Maryland, 11; Minnesota, 12; Nebraska, 2; New Hampshire, 6; Oregon, 1; Rhode Island, 3; Tennessee, 1; Texas, 3; Vermont, 3; Virginia, 1; Washington, 1; Wisconsin, 7.

[3] Includes establishments distributed as follows: Arkansas, 1; Georgia, 7; Iowa, 1; Kansas, 2; Kentucky, 11; Louisiana, 6; Maine, 4; Maryland, 16; Minnesota, 8; Nebraska, 1; New Hampshire, 7; North Carolina, 1; Rhode Island, 4; South Carolina, 1; Tennessee, 1; Texas, 7; Vermont, 5; Virginia, 3; Wisconsin, 10.

[4] Includes establishments distributed as follows: Delaware, 1; District of Columbia, 1; Georgia, 1; Iowa, 1; Kansas, 1; Kentucky, 6; Maine, 5; Maryland, 13; Minnesota, 6; New Hampshire, 8; North Carolina, 1; Rhode Island, 1; Tennessee, 2; Texas, 1; Vermont, 3; Virgina, 1; Wisconsin, 4.

Throughout the twenty-five years covered by the table the state of New York has been the leader in the production of musical instruments, and at the end of the period produced instruments, materials, etc., valued at nearly twice that of the output of the state second in importance, Illinois. The progress of the latter state in the industry, however, has been remarkable. At the census of 1880 the manufacturers of musical instruments in Illinois produced an output valued at only $694,975 and twenty-five years later an output valued at $13,997,728, or an increase in value of nearly nineteenfold during the period. At the census of 1880 Massachusetts was a fairly close second in the industry, but since that date has made comparatively slight gains, with the result that by 1900 the state was supplanted by Illinois, dropping to third place, which position the state maintained at the census of 1905. At the census of 1905 Ohio ranked fourth in the value of products, with an output valued at $3,714,255, which represented an increase of more than twenty-one fold over the value reported in 1880.

The development of the export and import trade in musical instruments is compared in Table 5 with the growth in the industry in the United States as measured by the value of the products reported at each census from 1870 to 1905.

TABLE 5.—*Musical instruments, attachments, and materials—value of exports and imports compared with value of domestic production: 1870 to 1905.*

CENSUS.	Value of domestic production.	EXPORTS.[1]		IMPORTS.[1]	
		Value.	Per cent of domestic production.	Value.	Per cent of domestic production.
1905	$69,574,340	[2] $3,230,982	4.6	[2] $1,366,285	2.0
1900	[3] 44,514,463	1,958,779	4.4	1,090,541	2.4
1890	36,863,169	1,105,134	3.0	1,703,129	4.6
1880	19,254,739	811,177	4.2	917,778	4.8
1870	13,905,908	267,400	1.9	[4] 1,050,218	7.6

[1] Bureau of Statistics, Department of Commerce and Labor, "Commerce and Navigation of the United States."
[2] Fiscal year ending June 30, 1904.
[3] Includes products valued at $95,485 not included in the general tables.
[4] Figures are for 1872, the first year musical instruments were reported separately.

The percentages in the table should not be considered without some important reservations. The fact that there are large duplications of value, as set forth in the discussion of Table 2, in the census totals forbids the use of the percentages except as an indication of general tendencies. An additional reason for care in this respect is the fact that the figures for exports and imports cover fiscal years, whereas census values cover calendar years, with the exception of 1900, when the census year ended May 31. The table indicates, then, that while the ratios of the value of imports of musical instruments to the value of such products manufactured in the United States have steadily decreased for the census years since 1870, the corresponding ratios of the value of exports of the same nature have increased for this period. The value of products manufactured increased fourfold, the value of exports elevenfold, while the value of imports increased only 30.1 per cent. At the census of 1870 foreign manufacturers sold to this country musical instruments valued at nearly four times as much as the manufacturers of these products in the United States shipped to foreign countries, but at the census of 1905 this condition was reversed and the value of exports was over twice as great as the value of imports of musical instruments.

Foreign markets are being more and more closely studied by musical instrument manufacturers, especially by piano and organ makers. When an instrument is designed to be shipped to some portion of the tropics, the woodwork is coated with a moisture-resisting varnish, veneer is avoided, all glued work is reenforced, felt parts are dipped in a poison solution to prevent ravages of insects, and other precautions tending to the preservation of the instruments are taken.

Undoubtedly the exports of musical instruments would be much greater were it not that piano and organ manufacturers have in some instances found it more advantageous to establish branch factories abroad, to carry out the ideas and methods of American production gauged to suit the requirements of the foreign trade, thus saving duties and obtaining the advantage of less expensive labor.

In the sections which follow, statistics of capital, labor, materials, etc., are omitted, the foregoing tables in this section presenting the essential details concerning these particulars. Moreover, the detailed summaries at the close of this report present the statistics for each industry in as refined a form as the statistical returns for the manufacture of musical instruments allow.

The following pages show the production of the various musical instruments, attachments, and materials, by kind and value, in as great detail in each case as conditions permit, and indicate the distribution of the production among the states, together with the principal centers of each industry within the states. In addition, matter descriptive of the different varieties of instruments and of the latest forms which have appeared is included.

PIANOS.

The statistics in this section include the manufacture of finished pianos of all kinds, also self-playing and street pianos, cabinet piano players, and piano playing attachments. The manufacture of piano materials, apart from factories reporting the finished instruments, having grown to be a considerable industry in itself, is presented separately in a later section.

The piano manufacturer generally buys certain portions of his instruments ready made, inasmuch as fac-

tories equipped for manufacturing certain parts can generally make them more economically than a piano factory. Some makers, however, manufacture the principal parts of their pianos, even selecting the wood that enters into the construction of the instrument. In compiling statistics relating to the industry it has been impossible for the Census Office to recognize any distinction of this kind.

Table 6 presents a comparative summary of the value of the different varieties of pianos manufactured in the United States as reported at the censuses of 1900 and 1905, showing the percentage each class is of the total value and the per cent of increase during the five-year period.

TABLE 6.—*Pianos, including piano players and attachments—kind and value, with per cent of total and per cent of increase: 1905 and 1900.*

KIND.	1905		1900[1]		Per cent of increase.
	Value.	Per cent of total.	Value.	Per cent of total.	
Total	[2] $43,527,543	100.0	$27,692,160	100.0	57.2
Upright pianos	37,397,674	85.9	25,294,297	91.4	47.9
Grand pianos	3,661,423	8.4	1,701,420	6.1	115.2
Square pianos	12,150	(3)	28,950	0.1	[4] 58.0
Self-playing and street pianos, piano players, and attachments	2,456,296	5.7	667,493	2.4	268.0

[1] Represents value of pianos, etc., reported by all classes of establishments.
[2] Includes piano players valued at $25,488, made by establishments engaged primarily in the manufacture of piano and organ materials.
[3] Less than one-tenth of 1 per cent.
[4] Decrease.

At the census of 1905, compared with that of 1900, the proportion which the value of upright pianos formed of the value of all products shown in the table decreased, while the proportions which the value of grand pianos and the group of instruments including self-playing and street pianos, piano players, and attachments, formed of the total value increased. This was due to the rapid increase in the value of grand pianos and the last-named group, which increased at a much greater rate than the value of upright pianos.

Grand pianos were manufactured in 1905 to a value of $3,661,423, or 8.4 per cent of the total value reported for all products and attachments, and an increase of 115.2 per cent over the value reported in 1900, which constituted 6.1 per cent of the total value for all classes of pianos, players, and attachments. Piano players and attachments show the remarkable increase of 268 per cent in value of product reported. The growing importance of this class of products has been a feature of the piano industry during the past five years, and the manufacture of the group of instruments composing it has been accorded separate treatment in another section of this report.

Excluding the product of square pianos, piano players and attachments, Table 7 shows the number and value of upright and grand pianos manufactured in selected states in 1905 in comparison with the census of 1900, together with the percentage the value of product reported for each state is of the United States total.

TABLE 7.—*Pianos, upright and grand—number and value, with per cent of total value, by states: 1905 and 1900.*

[1] Represents number and value of pianos reported by all classes of establishments.
[2] Includes states as follows: California, Colorado, Indiana, Kentucky, Louisiana, Maine, Maryland, Michigan, Minnesota, Missouri, Nebraska, New Hampshire, New Jersey, Pennsylvania, West Virginia, Wisconsin.
[3] Includes states as follows: California, Colorado, Indiana, Kentucky, Maine, Maryland, Michigan, Minnesota, Missouri, Nebraska, New Hampshire, New Jersey, Pennsylvania, Tennessee, Vermont.

Table 7 shows that 85,171 more upright pianos and 3,121 more grand pianos were manufactured in the United States during the year ending December 31, 1904, than during the year covered by the census of 1900. At the census of 1905, establishments located in the state of New York reported the manufacture of 96,985 upright pianos, or more than one-third of the entire number reported for the United States. New York city is the principal center in the United States for the manufacture of pianos; 82,532 uprights and nearly all the grands reported for the entire state were manufactured in that city, the aggregate product being greater than that reported for any state other than New York.

At both censuses shown in the table, Illinois ranked second in the production of upright pianos. Chicago is the great center of the industry in this state, and at the census of 1905, 42,933 upright pianos were reported by manufacturers at Chicago.

In the manufacture of upright pianos Massachusetts ranks as the third state, with a production valued at $4,022,237, an increase of 26.6 per cent over the value reported for 1900. Boston, the third city in the United States in the piano industry, reported the manufacture of 12,989 uprights and grands during 1904, to a total value of $3,266,177. Cambridge, Mass., also manufactured pianos to a considerable extent.

The concentration of the manufacture of upright pianos in the 3 leading states is marked, but the table indicates a slight decline in this respect. At the census of 1900, 77.9 per cent of the total number of upright pianos produced were manufactured in these 3 states, but by 1905 this proportion had decreased to 75.2 per cent. In the manufacture of grand pianos New York and Massachusetts produced 79.5 per cent of the total number reported at the census of 1900. The ascendancy of these 2 states in the manufacture of this variety of pianos has increased, since in 1905 the proportion increased to 81.2 per cent.

In 1900 there were manufactured in the United States 101 square pianos, valued at $28,950. In 1905, as far as manufacturing was concerned, the square piano was practically obsolete. There were, however, 43 square pianos made in the United States during the census year, by 3 companies upon special order, with a total value of $12,150.

The grand is conceded to be the superior instrument as regards tonal quality and musical results, but the upright is the more popular type, in that it occupies less space and is not as expensive as the grand. The apparent difference between the two is the horizontal position of the frame, sounding board, and strings of the former, as compared with the vertical construction of the latter, but the essential and most important differences are the greater length of strings, larger sounding board, and action method of the grand piano in comparison with that of the upright instrument. Piano manufacture has become standardized to a great extent, the same style piano of different factories usually possessing but few distinguishing outer characteristics other than the name on the fall board. Although practically similar in design, there is, however, a great difference between the high grade pianos and those of a lower grade. This difference is not only in the quality of materials and workmanship, but in the tonal results obtained through the expert assembling and regulating of the various parts into the perfect instrument. The best manufacturers thoroughly inspect every piano before it is allowed to leave the shop. This painstaking care and steadfast regard for the quality of each instrument has come to be recognized and appreciated, not only by dealers and agents, but by the purchasing public.

There are many dealers in musical instruments that have pianos made for them under contract with manufacturers who turn out what is known by the trade as the stencil piano, any name desired being placed on the plate, the dealer generally assuming the responsibility for the qualities of the piano.

In recording the various steps in the manufacture of a high grade piano the selection and seasoning of the various kinds of wood is the first and one of the most important. Only those grains and textures are used which have been found to possess the resonant quality necessary for the production of the desired tones. The wood used is almost entirely of American growth, the only notable exceptions being the expensive veneers for the case and the ebony for the black keys. The seasoning of this lumber requires several years, as the condition of the wood is a very important consideration in obtaining the best results.

This seasoned wood is sawed into widths, and the parts are usually made of a number of these widths fitted and glued together in order to withstand the influence of atmospheric changes, to obtain the best tonal results, and to add to the strength. Very few metal bolts or screws are used in the manufacture of a piano, even the timbers of the framework being glued together under heavy pressure. It is found that better results are thus obtained, as the glue properly applied makes a permanent joint, whereas bolts or screws are liable to work loose in their fittings.

The heavy wooden framework of a grand piano and that of an upright are necessarily different in form and construction, but the principles used are the same, for the solid, massive construction of the frame must assist the metal plate in bearing the strain of the strings.

The plate is a casting of metal, principally iron, and is made to fit over the frame. This portion of the piano is very generally manufactured by foundry and machine shops which make a specialty of piano plates and piano hardware. The smoothing down, machine drilling, and finally the bronzing and japanning of the plate are the important operations in the preparation of this casting for use in the pianos.

The spruce pine used in the sounding board is the subject of most careful selection, and the building of this slightly convex and highly sensitive wooden surface and the arrangement of the bridges may be considered among the delicate features of piano manufacture.

The sound production is caused by string vibration, and the wire used, necessarily of great elasticity and of highest grade, is in some instances purchased abroad. The laying out of the scale, arranging the length and weight of wire according to absolute rule, requires expert ability as well as genius. The action, or striking mechanism, the carefully balanced key, the felt covered hammers and dampers, and many other delicately adjusted parts include numerous perfected contrivances. Toning or voicing the piano to produce the tone shadings required is done by softening the felt of the hammers with needles.

The setting up or assembling of the instrument, and the regulating of the many parts to make a harmonious whole is the next step in piano manufacture. The sounding board and plate are attached to the framework, the wires are properly strung and chipped or tuned in a preliminary manner, the keyboard and action are then set in and adjusted, the final tuning of the strings is gone over by experts, and the combined results carefully tested.

Great care is expended in the finish of the case, inasmuch as the instrument is designed to please the eye as well as the ear. It is varnished, sandpapered, and rubbed until a highly polished surface is obtained. Foreign taste prefers the dull finish, and by many this is considered more artistic.

ORGANS.

This instrument is of two principal types, the reed organ, or melodeon, and the pipe organ, the former type being a free reed instrument in which musical tones are produced by thin tongues of brass or steel set in vibration by currents of air, while the latter instrument has a series of pipes of different materials, size, and construction, in which columns of compressed air are caused to vibrate, producing tones of great purity and volume. The ordinary reed organ is small and comparatively inexpensive, while the pipe organ is a much larger instrument and considerably different in structure, and capable of far greater volume and variation in character of tone.

The organ produces a sustained tone which endures as long as the air passage leading to the particular reed or pipe, controlled by the depression of a key, is kept open, admitting a current of air; whereas the tone of a piano continues only during the natural vibration of the string. The forms and measurements of the keyboards of both styles of organs and the piano conform to the same standard, and the music is for the most part interchangeable.

In playing the reed organ the feet are generally used to operate the bellows, while with the pipe organ, which is always provided with hand, mechanical, or other blowing apparatus, the feet are used to manipulate a pedal clavier arranged to command certain pipes and combinations in the same manner as the manual claviers are arranged to command the other pipes and combinations.

Statistics concerning the value of reed organs, pipe organs, and street and self-playing organs manufactured during 1900 and 1904 are shown in Table 8, together with the per cent each class is of the total valuation and the per cent of increase during the five-year period.

TABLE 8.—*Organs—kind and value, with per cent of total and per cent of increase: 1905 and 1900.*

KIND.	1905		1900[1]		Per cent of increase.
	Value.	Per cent of total.	Value.	Per cent of total.	
Total	[2] $6,774,433	100.0	$5,689,033	100.0	19.1
Reed organs	4,212,953	62.2	4,088,073	71.9	3.1
Pipe organs	2,088,193	30.8	1,188,696	20.9	75.7
Street and self-playing organs, and other varieties	473,287	7.0	412,264	7.2	14.8

[1] Represents value of organs reported by all classes of establishments.
[2] Includes reed and pipe organs valued at $149,114 made by establishments engaged primarily in the manufacture of other products; of this value, $69,114 represents organs made in establishments other than musical instruments, attachments, and materials.

The principal feature of the table is the increase since 1900 in the value of pipe organs manufactured. This increase, however, was not sufficient to place the manufacture of pipe organs on the same plane of importance as that of reed organs, which dominated the industry at both censuses, although to a decreasing extent.

Statistics regarding the number and value of reed organs for the United States and selected states are given in Table 9, for the censuses of 1900 and 1905.

TABLE 9.—*Reed organs—number and value, with per cent of total value, by states: 1905 and 1900.*

STATE.	Census.	Number.	VALUE.	
			Amount.	Per cent of total.
United States	1905	[1] 114,675	$4,212,953	100.0
	1900	[2] 107,830	[2] 4,088,073	100.0
Illinois	1905	57,219	1,787,220	42.4
	1900	53,643	1,715,876	42.0
Indiana	1905	3,835	145,476	3.5
	1900	3,697	173,339	4.2
Massachusetts	1905	2,073	150,883	3.6
	1900	3,323	190,582	4.7
Michigan	1905	12,381	511,009	12.1
	1900	9,624	397,198	9.7
Ohio	1905	1,949	94,577	2.3
	1900	1,643	98,572	2.4
Pennsylvania	1905	5,715	242,059	5.7
	1900	6,240	275,438	6.7
All other states	[3] 1905	31,503	1,281,729	30.4
	[4] 1900	29,660	1,237,068	30.3

[1] Includes 1,610 reed organs, valued at $50,900, reported by establishments engaged primarily in the manufacture of products other than musical instruments, attachments, and materials.
[2] Represents number and value of reed organs reported by all classes of establishments.
[3] Includes states as follows: Connecticut, Kentucky, Maryland, Minnesota, New Jersey, Oregon, Vermont, West Virginia.
[4] Includes states as follows: Connecticut, Maryland, Minnesota, New Jersey, New York, Vermont, Virginia.

The table shows a marked localization of the industry in Illinois, the value of the reed organs manufactured in this state at the census of 1905 constituting 42.4 per cent of the aggregate value reported for the entire United States. In Illinois the industry is localized principally in Chicago, which produced 37,622 reed organs, or 65.8 per cent of the number manufactured in the state at the census of 1905. Evidently the middle West is the principal seat of the production of reed organs, for Michigan, Indiana, and Ohio also reported a large production of these instruments, the combined value of the products of the 4 states at the census of 1905 constituting 60.2 per cent of the value of the total production for the United States. In both Massachusetts and Pennsylvania the production of reed organs is declining.

The American reed organ, with perhaps a single exception, is a suction instrument, while the harmonium, or European style of reed organ, operates with air pressure. About 1635, a harmonium maker in Paris invented the suction instrument, but the first of this class of organs manufactured in the United States was made in Boston. These have since become known as

the American reed, or cabinet, organs, although at first designated as melodeons. Rapid progress has been made in the construction of the American reed organ, and it is to-day recognized as a special type of instrument, all organs of this kind now built or used abroad being designated "American organs."

Each reed organ possesses a series of stops controlling individual sets of reeds, and these stops, when drawn, cause the different combinations of tones desired. When the stops are drawn, the pressure on the key opens a pallet or valve permitting the passage of air through the reed cell, causing the reed to vibrate and produce its characteristic note. The reeds are vibratory tongues of brass or steel riveted upon perforated metallic plates, and placed in separate wooden cells made on the edges of what is called the reed board, which latter rests upon the top of the wind chest directly under the keys. There may be more than one set of reeds, and in that case one is placed in front of the other on the reed board, or if more than two, they are placed one over the other. The air pressure is ordinarily produced by a pair of exhausters, operated by the foot pedals, which exhaust the air from a reservoir under a spring tension passage communicating between this reservoir and the air chambers of the instrument containing the valve mechanism.

In addition to the keys, stops, and pedals, there are one or sometimes two knee swells or divided couplers, as they are sometimes called, whereby reeds an octave above or below the keyboard center are caused to sound in addition to the reeds directly connected with the depressed keys. Thus in operating an organ various stops and devices are used to increase or diminish quantity and to vary the character of the tone, inasmuch as no control is possible from the pressure on the keys other than to open the passage of air to certain reeds.

The timbre, or quality, of the tone is regulated by the opening in which the reed vibrates and by the size and form of the channel above the reed and its pallet hole through which the air passes, straining due to excessive or uneven operation of the foot pedal being obviated by a discharge pallet acting as a safety valve. The voicing and tuning are very important operations, the latter being obtained by filing or scraping the tongue of the reed and the former by twisting the tongue into certain curves which determine the quality of tone. The reed organ seldom gets out of tune, inasmuch as it is not susceptible to changes in temperature and atmospheric conditions.

The manufacture of the reed organ, like that of other musical instruments, is largely the result of experience and development. Probably the manipulation of the tongue of the reed to a proper size and curve and the determining of the size of the reed cells, etc., and the length and size of the qualifying cells, when such are used, are the most delicate of the intricate operations involved in its manufacture.

The vocalion is a reed organ approaching somewhat a pipe organ in its characteristic tone quality. Vocalion instruments are largely used in churches, and usually have a pedal base and often two manual claviers, or keyboards, conforming in appearance to the pipe organ. The difference between the ordinary reed organ and the vocalion is that in the latter the air current passes through qualifying cells and tubes before or after reaching the reeds.

There have also been manufactured a combination pipe and reed organ, desk and reed organ, and other somewhat unusual compound forms of the instrument. Almost all the materials used in reed organ construction are strictly American products, with the exception of ivory and ebony. Very little ivory is now used on the keyboard of reed organs, celluloid being substituted in its place, while a stained wood is generally used instead of ebony for the black keys. Very little expensive veneer is used on these instruments, unless by special order, as it greatly increases the cost of the instrument. Unlike the average piano manufacturer, organ makers usually manufacture all parts of their instrument with the exception of reeds and keys, the making of which is really a separate industry.

Statistics of pipe organ production in this section do not include instruments fitted with devices for automatic playing, inasmuch as these will be included under the head of self-playing instruments. Table 10 presents the number and value of pipe organs built in selected states, and shows the per cent the value of products for each state is of the total value reported for the United States at the censuses of 1900 and 1905.

The number of pipe organs manufactured is not great, but as a rule they are large and comparatively expensive. The table indicates that their production is not centered to a very marked degree in any one state. The value of the organs produced in Massachusetts at the census of 1905 formed 24.9 per cent of the total value for the United States, but both Illinois and Ohio contributed largely to the total, and the numerical output in the case of Ohio equaled and in the case of Illinois exceeded that of the leading state. The average value of the organs built by Massachusetts makers was, therefore, considerably larger than that of the organs manufactured in either Illinois or Ohio. Boston is one of the chief centers for the manufacture of high-grade pipe organs, 60 of these instruments having been built in this city during 1904, with a value of $313,220, a greater valuation than was reported by any state in the United States other than Massachusetts. Pipe organs were also made in Springfield, Waltham, and Cambridge, Massachusetts.

In Illinois, Chicago reported about two-thirds of the total value of pipe organs manufactured in this state, while in Ohio, which has advanced rapidly in

this manufacture, Pomeroy, Alliance, and Cleveland produce the greater part of the pipe organs manufactured in the state. Vermont, Pennsylvania, Maryland, New York, and Connecticut are the next 5 states, ranked according to value of pipe organs built during 1904. Neither Vermont nor Connecticut can be shown in the table, as to do so would reveal individual operations.

TABLE 10.—*Pipe organs—number and value, with per cent of total value, by states: 1905 and 1900.*

STATE.	Census.	Number.	VALUE.	
			Amount.	Per cent of total.
United States	1905	[1]936	[1]$2,088,193	100.0

	1900	8	15,475	1.3
All other states	[3]1905	251	435,071	23.2
	[4]1900	114	221,159	18.6

[1] Includes 35 pipe organs, valued at $96,214, made by establishments engaged primarily in the manufacture of other products. Of this value, $18,214 represents pipe organs made by establishments other than musical instruments, attachments, and materials.

[2] Represents number and value of pipe organs reported by all classes of establishments.

[3] Includes states as follows: California, Connecticut, Delaware, Indiana, Iowa, Kentucky, Maine, Michigan, Minnesota, Missouri, New Jersey, Rhode Island, Vermont.

[4] Includes states as follows: California, Colorado, Connecticut, District of Columbia, Indiana, Iowa, Kentucky, Michigan, Minnesota, Missouri, New Hampshire, New Jersey, Rhode Island, Texas.

The pipe organ is often spoken of as being the largest, most expensive, and most perfect of all musical instruments, and the methods of its manufacture are of considerable interest. Almost every pipe organ is practically built to order to accord with the architecture or acoustic qualities of the room or auditorium in which it is designed to be placed. The ornamental work of the pipe organ is sometimes put in by the building contractors, who are in no way identified with the organ builders.

One complete stop of one rank of pipes in the modern organ consists of 61 notes for the manual clavier and 32 for the pedal clavier, and there are as many stops as may be desired according to the size and cost of the organ; in some instances there are 100 or more. These pipes are made of wood or metal, the wood being carefully selected of various growths, and the metals, chiefly zinc, tin, and lead, being used in alloys according to the different qualities of tone desired. The arranging of the shape and size of the pipes is an operation in which experience and knowledge on the part of the builder are necessary to the manufacture of a successful instrument. The voicing and tuning of these pipes are invariably done before they are set up in the organ, and this operation is of great delicacy. Final tuning and regulating are done after the pipes are placed in the finished instrument.

The bellows of a pipe organ must be of exactly sufficient capacity to feed all the pipes, and therefore varies in construction according to the size of the organ. The operation of the bellows may be by hand, by hydraulic power, or by electricity, in which latter instance a current of from 100 to 200 volts in strength is necessary. There is an electric fan feeder recently patented which is said to be very successful in operation and which takes up much less room than the ordinary class of feeders, but the ordinary compound bellows is used in the majority of organs, and almost altogether in those built in 1904. The air does not pass directly to the pipes, but is generally led first into a regulator bellows, which makes the pressure more even and regular in strength, after which it is conveyed to the wind chest, and is then caused to pass into the pipes by the opening of valves controlled by the key or playing mechanism.

The tracker organ, in which the pallets or valves leading from the wind chest to the pipes are opened direct from the keys by means of trackers or levers, has been largely superseded by the more modern pneumatic and electric action, although there are many of the older style still in use, and some builders still make small tracker organs. During 1904 the principal pipe organ action used was of the tubular pneumatic type, in which the depression of the keys opens certain valves, causing air pressure to open larger valves, admitting the air from the wind chest to the pipes.

Probably the most recent development in pipe organ construction is the electric action, which is operated either by a storage battery or by a small generator connected with the bellows motive power. Depression of a key causes electrical contact, allowing the current to pass through a magnet in the wind chest or pallet box, which magnet operates a primary valve connected with a larger valve, which, being open, allows passage of air, thereby causing the pipe to speak. Each key of both manual and pedal claviers is fitted with this arrangement of magnet, air cells, valves, etc., and the action is simultaneous with the pressure on the key or pedal. The use of electricity in the action mechanism allows the instrument to be played with an even and light pressure on the keys, whereas, in the older style tracker organ, to operate some combinations required considerable strength. Another advantage in an electrically operated organ is that the key case, or console, may be placed at any distance from the organ proper, inasmuch as the power is transmitted by wires to the valve mechanism con-

nected with the pipes. This arrangement is also possible in the exclusive tubular pneumatic organ, although the distance capable of being covered is necessarily somewhat limited.

SELF-PLAYING AND STREET PIANOS AND ORGANS, AND PIANO PLAYERS AND ATTACHMENTS.

The statistics concerning the kind and value of self-playing and street pianos and organs, cabinet piano players, and playing attachments, presented in preceding sections in connection with the manufacture of pianos and organs, are shown in greater detail in the three tables following. Table 11 is a comparative summary showing the value reported for each class during 1900 and 1905, with the per cent of increase during the five-year period and the per cent each class is of the total value.

TABLE 11.—*Self-playing and street pianos and organs, and piano players and attachments—kind and value, with per cent of total and per cent of increase: 1905 and 1900.*

KIND.	1905		1900		Per cent of increase.
	Value.	Per cent of total.	Value.	Per cent of total.	
Total	[1] $2,929,583	100.0	$953,772	100.0	207.2
Piano players and piano playing attachments	2,029,754	69.3	607,873	63.7	233.9
Self-playing pianos and organs	849,813	29.0	317,569	33.3	167.6
Street pianos and organs	50,016	1.7	28,330	3.0	76.5

[1] Includes piano players valued at $25,488 made by establishments engaged primarily in the manufacture of piano and organ materials.

Large increases are shown for each group of products, but the leading feature of the table is the increase since 1900 of 233.9 per cent in the manufacture of piano players and attachments, which indicates the growing popularity of automatic piano playing.

Table 12 presents the number and value of piano players and piano playing attachments manufactured in the United States at the censuses of 1900 and 1905 and the per cent each class is of the total value at both censuses.

TABLE 12.—*Piano players and piano playing attachments—number and value, with per cent of total value: 1905 and 1900.*

KIND.	Census.	Number.	VALUE.	
			Amount.	Per cent of total.

Piano playing attachments	1905	2,982	152,780	7.5
	1900	922	87,734	14.4

[1] Includes 243 piano players, valued at $25,488, made by establishments engaged primarily in the manufacture of piano and organ materials.
[2] Represents number and value of piano players and piano playing attachments reported by all classes of establishments.

According to the census designation, the piano player is a separate cabinet instrument which must be attached to a piano to be used. The value of product reported for this class of automatic players in 1905, as compared with 1900, increased 260.9 per cent. Connecticut ranks first in the manufacture of these instruments, with Meriden as the center, while New Jersey, Michigan, New York, and Illinois are respectively the second, third, fourth, and fifth states in order of principal production.

Piano playing attachments, or interior players, as they are sometimes called, were manufactured to a considerable extent at the census of 1905, when a product valued at $152,780 was reported, an increase of 74.1 per cent over the $87,734 reported in 1900. The state of New Jersey reports the principal production of interior players, with New York and Connecticut second and third in rank. The piano playing attachments thus reported do not include the entire product, inasmuch as there were manufactured 2,569 self-playing pianos and organs, as shown in Table 13, the value of which includes the value of the self-playing mechanism contained in the instrument.

Table 13 presents the number and value of self-playing pianos and organs manufactured in the United States as reported at the censuses of 1900 and 1905, with the per cent each is of the total value reported at each census.

TABLE 13.—*Self-playing pianos and organs—number and value, with per cent of total value: 1905 and 1900.*

KIND.	Census.	Number.	VALUE.	
			Amount.	Per cent of total.
Total	1905	2,569	$849,813	100.0
	1900	1,962	317,569	100.0
Self-playing pianos	1905	1,868	417,382	49.1
	1900	224	44,745	14.1
Self-playing organs	1905	701	432,431	50.9
	1900	1,738	272,824	85.9

The great advance in the last five years in the manufacture of pianos containing self-playing mechanism is shown by the fact that the value of these instruments increased from $44,745 to $417,382, or 832.8 per cent, during the period. New York state leads in this manufacture, reporting 1,506 self-playing pianos, valued at $314,682, or 75.4 per cent of the total value of products. New Jersey, Missouri, Connecticut, and Illinois also report the manufacture of self-playing pianos, ranked in the order named. The total number of piano players, piano playing attachments, and self-playing pianos shown by Tables 12 and 13 was 22,502, compared with 6,382 reported in 1900, which comparison indicates the increased use of all kinds of piano playing mechanism, and doubtless another census will show a still greater advance, inasmuch as

public attention is being turned in this direction by the satisfactory results obtained by these devices.

The value of the self-playing organs manufactured increased during the five years, but the number decreased. This decrease in number is explained by the fact that these instruments are now largely of the pipe organ variety, which are more expensive than reed organs, the latter not being fitted with playing mechanism to as great an extent as in 1900, attention being directed more to piano playing devices. In the manufacture of self-playing organs New Jersey ranks first, Massachusetts second, and New York third, while 8 other states also show a product of this style of musical instruments.

Piano players and playing attachments are becoming quite numerous, and many ingenious devices have been invented. The cabinet player, with felt plungers to strike the keys of the ordinary piano, was the first to be generally used and is still very popular, especially for use in playing a grand piano. Most of the instruments and attachments are now operated primarily by pneumatic pressure or suction, or by a combination of pneumatic and electric action. The air, passing through the holes of the perforated music paper running over corresponding holes in a tracker board, is communicated, usually by means of rubber tubes, to the playing mechanism. There are, however, ingenious electric devices for automatic piano playing which have been prominently displayed and are now being manufactured, but during the year 1904 the action used in playing mechanism was principally pneumatic.

The organ lends itself more readily to automatic playing because of its valvular arrangement, the quantity and quality of tone being controlled by stops and knee swells, rather than by the strength and character of stroke, as in piano playing. The wind motor furnishing pneumatic pressure or suction may be operated by electricity, an ordinary storage battery being generally used to furnish the current required, which is not more than from 4 to 8 volts in strength. In a self-playing organ the automatic mechanism, by means of this pneumatic action, controls the organ action in technically the same manner that it would if played by hand, except that the air control does not operate the keys but is taken directly to the valves which ordinarily would be controlled by the keys. It is claimed that there are no effects possible to organ playing by hand which may not be obtained by self-playing mechanism under expert guidance, and it may readily be seen that orchestral arrangements too complex for one organist can be executed by the playing attachment.

The piano case containing a playing attachment is so constructed that when closed up it is an ordinary piano which can be played by hand. If it is desired to use the instrument automatically, a panel in the upper part of the case may be opened and a roll of music fitted in and attached to run over the tracker board and wind on a receiving spool. By letting down a hinged panel in the lower portion of the instrument, the pedal arrangement is disclosed by means of which wind power may be provided to operate the bellows furnishing pneumatic power to the playing mechanism. Thus the upright piano is in this combination instrument capable of being operated either by hand or by automatic action.

Expression is put into the automatically played music by means of levers, and accellerando and ritardando as well as forte and pianissimo effects are thus obtainable, and modern devices enable individual notes or a certain air to be made prominent with the accompaniment subdued. This ability to bring out a theme or melody is a new power which has been given the automatic instrument.

An electric playing mechanism using about one-third the power of a small incandescent lamp has been recently put on the market, but none was reported as manufactured during 1904, except in experimental work. This apparatus does away with the necessity of pumping a bellows, and is considered successful not only in convenience and correct operation but the claim is also made that music played by this attachment may be transposed to a higher or lower key by a simple mechanical arrangement. This player was exhibited by the United States Patent Office at St. Louis in 1904 and at the Lewis and Clark Exposition at Portland in 1905.

The perforated music for automatic attachments and players, whether cabinet or interior, pneumatic or electric, is becoming standardized to a great extent and the same music generally may be used with any style of player. There are, however, music arrangements in two sizes, taking in a range of six and one-half to seven and one-third octaves. There is an expensive attachment which marks this music paper from the actual playing on a piano, but more accurate and satisfactory results are obtained by marking the music from the original score by hand, on a master roll which is proof read, tested, and corrected.

Expression marks are decided by interpretation experts and on important selections the composer's ideas are obtained wherever possible. The music is then cut automatically, 15 rolls at a time, from the perfect master roll and the expression and other marks are put on from a cardboard pattern. Extensive classification has been made of the many selections and arrangements in perforated music, and circulating libraries and educational departments in the principal cities have catalogues of roll music listed in grades.

PIANO AND ORGAN MATERIALS.

The value of piano and organ materials is shown separately for the first time at this census. These statistics do not include the total value of these products, for only those factories which manufacture parts and materials are included, the parts made by factories manufacturing the finished instrument being included with pianos and organs.

It is probably true that this first presentation of the subject may not include certain piano parts made by establishments primarily engaged in the manufacture of other products, and this fact should be taken into consideration in the examination of the figures. Certain foundry and machine shops may have cast piano plates or other piano hardware which are not specified separately from the other products of the establishment, or furniture manufacturers may have made cases or piano stock to some extent not specifically mentioned in their reports, and such partial products would not be included in the value reported for piano and organ parts and materials.

Table 14 is a summary for the United States and selected states showing the value of piano materials and parts, and all other products including organ materials and parts, and piano and organ materials and parts, not specified, and other products of a miscellaneous nature.

TABLE 14.—*Piano and organ materials—value of products, by states: 1905.*

STATE.	Total.	Piano materials and parts.	All other products, including organ materials and parts, and piano and organ materials and parts, not specified.
United States	[1] $13,128,315	$11,397,907	[2] $1,730,408
Connecticut	2,397,822	1,653,286	744,536
Illinois	998,239	655,911	342,328
Massachusetts	2,165,393	1,874,014	291,379
New Jersey	288,959	285,559	3,400
New York	5,226,947	5,142,812	84,135
Ohio	1,412,839	1,295,905	116,934
All other states [3]	638,116	490,420	147,696

[1] In addition, piano and organ materials and parts to a value of $572,686, unfinished pianos to a value of $179,547, and unfinished organs to a value of $152,621 were made by establishments engaged primarily in the manufacture of pianos and organs; and piano materials to a value of $281,016 were made by establishments engaged primarily in the manufacture of musical instruments and materials, not specified.

[2] Includes organ materials and parts to a value of $581,373, and piano and organ materials and parts, not specified, amounting to $647,612.

[3] Includes states as follows: California, Indiana, Michigan, New Hampshire, Pennsylvania, Vermont.

The product of establishments manufacturing piano and organ materials and parts in the United States is divided in the following proportions: Piano materials and parts, 86.9 per cent; organ materials and parts, 4.4 per cent; piano and organ materials and parts, not specified, 4.9 per cent; and all other products, 3.8 per cent. The principal item of this manufacture is therefore piano materials and parts. It is interesting to note that the value reported under this head is 26.2 per cent of the total value of pianos manufactured in the United States during 1904. This indicates the tendency to specialization in the manufacture of piano materials and parts.

As New York predominates in the piano industry, it is natural that this state should also lead in the manufacture of piano materials and parts. The chief center is New York city, where piano materials and parts were manufactured in 1904 to a value of $3,491,493, which amount is nearly one-third of the United States total for this class of products. This amount includes the product of two supply factories on Long Island, where piano parts are manufactured, and eventually transferred to another factory belonging to the same establishment, to be assembled. Tonawanda, Rochester, Dolgeville, Castleton, Brockport, and St. Johnsville and other towns in New York also report a considerable product of piano materials and parts. Massachusetts ranks second in this industry, the chief cities being Cambridge and Leominster. The third state in rank is Connecticut, where Ivoryton reports the principal production, with Stamford second. In Ohio, the fourth state in this industry, the localities of chief production are Springfield and Cincinnati. Chicago, Ill., Lisbon, N. H., and Grand Rapids, Mich., are also important centers.

Organ materials and parts are manufactured to only a small extent separate from the finished instrument. The principal localities for this production are Worcester, Reading, and Westfield, in Massachusetts; Chicago, in Illinois; Ivoryton, Mansfield, and Deep River, in Connecticut; and Alliance, in Ohio. At the census of 1905 the total value of the product for the United States amounted to but $581,373. The large item in Connecticut for all other products, including piano and organ materials, not specified, as shown in Table 14, is largely for piano and organ keyboards.

Table 15 presents statistics concerning the value of specific piano materials and parts manufactured in the United States, showing the per cent each item is of the total reported for this class of products.

TABLE 15.—*Piano materials and parts—distribution of value, by kind: 1905.*

KIND.	Value.	Per cent of total.
Total	$11,397,907	100.0
Actions and action parts	3,439,394	30.2
Cases and piano stock	2,732,493	24.0
Ivory and keys, including keyboards	2,048,795	18.0
Plates, hardware, and strings	2,023,646	17.7
Sounding boards and bridges	447,347	3.9
Piano materials and parts, not specified, including partially manufactured pianos for which a separate division of parts is not obtainable	706,232	6.2

The table shows that the manufacture of actions and action parts forms the most important branch of the production of piano materials and parts. New York state reports the manufacture of piano actions and action parts to a value of $2,160,614, which is 62.8 per cent of the total value reported for the entire United States. Of this amount New York city claims a value of $1,714,419, and a considerable product is also reported for Castleton, St. Johnsville, and Nassau, and other localities in New York state. Outside of New York state Cambridge, Mass., Ivoryton, Conn., and Chicago, Ill., are the chief centers for the manufacture of actions, and there are establishments also in Cincinnati, Ohio, Fort Lee, N. J., Rockford, Ill., and Boston, Mass.

Piano cases, frames, backs, and legs, including ribs, trusses, and trimmings, are manufactured to a value of $2,732,493, and of this amount $1,022,877 was for New York state, chiefly in New York city, Rochester, Brockport, Cortland, and Dolgeville, in the order named. Leominster, Arlington, and Westfield are the centers in Massachusetts, the second state in this manufacture.

The principal locality in the United States for the manufacture of piano ivory and keys, including keyboards, is Ivoryton, Conn., while Tonawanda, N. Y., and Cambridge, Mass., are respectively second and third.

Piano plates are manufactured very largely in Springfield, Ohio, New York, N. Y., Stamford, Conn., and are also reported in Chicago, Ill., as well as in a number of other cities in lesser values.

Sounding boards and bridges are reported chiefly by establishments located in Lisbon, N. H., and Dolgeville, N. Y., although several other localities reported considerable product.

Table 16 presents the kind and value of organ materials and parts manufactured by factories not reporting the finished instrument.

TABLE 16.—*Organ materials and parts—distribution of value, by kind: 1905.*

KIND.	Value.	Per cent of total.
Total	$581,373	100.0
Pipes, reeds, and reed boards	366,137	63.0
Ivory and keys, including stops, knobs, couplers, tremolos, etc	185,680	31.9
Organ materials and parts not specified	29,556	5.1

The principal organ parts which are reported as manufactured separate from the finished instrument are pipes, reeds, and reed boards. Chicago reported the principal manufacture of reeds and reed boards, with Worcester, Mass., second, while Reading, Mass., reported organ pipes to a considerable extent.

Tables 17, 18, 19, and 20, which follow, present detailed statistics, by states, for each of the four industries embraced in the group of musical instruments, attachments, and materials.

TABLE 17.—MUSICAL INSTRUMENTS, PIANOS—

		United States.	California.	Connecticut.	Illinois.
1	Number of establishments	249	6	8	36
2	Capital, total	$49,649,135	$65,770	$3,049,225	$14,908,172

PHONOGRAPHS AND GRAPHOPHONES.

Statistics concerning the manufacture of phonographs, graphophones, and supplies were presented in 1900 in connection with the special report on electrical apparatus and supplies,[1] inasmuch as this apparatus was invented and largely perfected by electricians, or those particularly interested in electricity. The only portion of the instrument, however, that is ever electrical in operation is the motor, which is sometimes arranged for attachment to the incandescent light wire or has a storage battery attachment, the current thus obtained furnishing the power.

For the reason, therefore, that this class of instruments may not properly be considered as electrical apparatus and as it is now considerably used in reproducing music and its introduction to the public is largely through the medium of music dealers, the statistics are presented with the report on the manufacture of musical instruments and materials. The figures given are not included with the combined statistics on musical instrument manufacture, but are presented in separate form and include not only the manufacture of the finished instrument but also phonograph and graphophone supplies and disk and cylinder records, when the same were manufactured by establishments classified under this head.

Table 21 is a comparative summary of statistics for the United States, showing the per cent of increase during the five-year period, 1900 and 1905.

TABLE 21.—*Phonographs and graphophones—comparative summary, with per cent of increase: 1905 and 1900.*

	1905	1900	Per cent of increase.
Number of establishments	14	11	27.3
Capital	$8,740,618	$3,348,282	161.0
Salaried officials, clerks, etc., number	537	144	272.9
Salaries	$666,489	$179,145	272.0
Wage-earners, average number	3,397	1,267	168.1
Total wages	$1,683,903	$608,490	176.7
Men 16 years and over	3,025	1,114	171.5
Wages	$1,564,625	$565,076	176.9
Women 16 years and over	364	146	149.3
Wages	$117,859	$42,914	174.6
Children under 16 years	8	7	14.3
Wages	$1,419	$500	183.8
Miscellaneous expenses	$1,653,762	$215,401	667.8
Cost of materials used	$4,161,136	$827,529	402.8
Value of products	$10,237,075	$2,246,274	355.7

There was an increase of but 3 establishments in the five years intervening between the two censuses, and, as these 3 establishments reported a very small product, the large increase in production has occurred without any corresponding increase in the number of establishments reporting. This concentration of manufacture in a few large companies is due to the possession of patents which enables them to retain the rights to sole production.

Table 21 shows that in 1900 the capital invested was 49.1 per cent larger than the value of products reported, while in 1905 the value of products was considerably larger, being 17.1 per cent more than the capital. This results naturally from the fact that at the last census the industry was in its infancy, and costly experiments were constantly being made which required the expenditure of large sums of money with, in some instances, comparatively little return. Experiments are still being made and expensive laboratories are maintained in the principal factories, where new materials are tested and other improvements are designed and worked out by experts; but in the main the production of phonographs and graphophones is past the experimental stage and their commercial position is assured. Thus at the census of 1905 the productive power of the capital invested was utilized much more completely than in 1900, and the alteration in the relation of capital to products at the two periods resulted.

The item of miscellaneous expense is apparently a very important factor in the cost of production of phonographs and graphophones. At the census of 1905 the amount expended for this item nearly equaled the expenditure for labor. This is due to the cost of extensive advertising and the large amounts expended to secure records of famous bands and professional soloists, items which are included in the total of miscellaneous expense.

The principal centers of the industry are Camden and Orange, N. J.; Bridgeport, Conn.; Toledo, Ohio; and New York city.

Table 22 is a summary of products of establishments manufacturing phonographs, graphophones, disk or cylinder records, and phonograph and graphophone supplies, as reported at the censuses of 1900 and 1905, showing the per cent each item is of the total for each census and also the per cent of increase during the five-year period.

TABLE 22.—*Phonographs and graphophones—products, by kind and value, with per cent of total and per cent of increase: 1905 and 1900.*

KIND.	1905		1900		Per cent of increase.
	Value.	Per cent of total.	Value.	Per cent of total.	
Total	$10,237,075	100.0	$2,246,274	100.0	355.7
Phonographs and graphophones	2,966,343	29.0	1,240,503	55.2	139.1
Disk and cylinder records	4,678,547	45.7	539,370	24.0	767.4
All other products	2,592,185	25.3	466,401	20.8	455.8

The total value of phonographs and graphophones manufactured in 1905 was but 29 per cent of the total product reported for the industry at that census, while the value of disk and cylinder records manufactured represented 45.7 per cent of the same total. In 1900 the proportions were reversed, the value of finished instruments manufactured amounting to 55.2 per cent of the total, and the value reported for

[1] Twelfth Census, Manufactures, Part IV, page 181.

disk and cylinder records to but 24 per cent of the total. This change in the relative importance of the two branches of the industry was not due to any falling off in the production of phonographs and graphophones, which increased largely during the five years, but to the far greater increase in the production of disk and cylinder records. As the machines themselves become more widely distributed, the manufacture of disk and cylinder records is sure to continue to increase at the same extraordinary rate. Every phonograph and graphophone sold creates a demand for records that results in sales which ordinarily far exceed in value the initial cost of the machine itself.

The value reported for this industry includes in some instances a product which can not be classed under either the finished instrument or disk and cylinder records. For instance, a large establishment in Philadelphia reports the exclusive manufacture of talking machine supplies, the value of which is included in Table 22 under the head of "all other products," and items of this nature are probably duplicated to a certain extent in the values reported for phonographs and graphophones by establishments manufacturing the finished product. In these latter establishments, under the heading materials used, there is reported a large expenditure for materials such as horns, cylinder cases, etc., which are reported as finished products of plants producing such supplies, and thus their values are included twice in the aggregate for the industry. It is impossible to measure the extent of this duplication, but its presence should be noted when the value reported for the industry is under consideration.

In addition to phonograph and graphophone supplies there is also included in "all other products" a number of miscellaneous articles not related to the industry—for instance, billiard balls and game markers, composition novelties, electrical specialties, numbering machines, etc.—reported by establishments whose principal product is phonographs, graphophones, records, and supplies. This value, however, is of little consequence in comparison with the grand total.

The history of the phonograph and graphophone can be found in the special report on electrical apparatus and supplies,[1] and therefore minute details will not be given in this report. Briefly stated, the principal features of the instrument are the motor, the recording and reproducing mechanism, and the record, which is flat or cylindrical according to the type of machine.

Electricity is sometimes used as motive power, especially for office dictation instruments, but the large majority of phonographs and graphophones manufactured are operated by clockwork with a tandem spring wind. The motor is arranged to turn the mandrel holding the record, and there is a delicately adjusted "governor" arranged to regulate the speed, thus retarding or accelerating the action as required.

In making a record the sound waves received in the horn of the instrument and transmitted through the sound passage, agitate the sensitive mica or glass diaphragm, which is about one one-hundred and fiftieth of an inch in thickness and from an inch and one-fourth to 2 inches in diameter. A small cutting chisel or point is attached to the diaphragm for the purpose of recording these vibrations on a blank wax record. This original or master record is then electrotyped for permanent use and duplicate records are made from an exact gold-plated copper mold negative.

The reproduction of sound from records is practically a reversal of the process of making. The reproducer point for use on cylinder records is a sapphire ball, and the sound markings are in the form of engravings about one one-thousandth of an inch in depth; whereas in a disk machine a metal reproduction needle is used and the markings are delicate zigzag lines about 100 to the inch. The stylus, resting on a revolving cylinder record, is moved rapidly up and down, agitating a horizontal diaphragm, while the needle of a disk machine is moved from left to right and vice versa, agitating a diaphragm attached to the needle obliquely with the record. This vibration produces the sound passage—sound waves which are practically identical with those originally communicated to the master record. The size and construction of the horn are important to successful results, inasmuch as it prevents the sound waves from becoming scattered. In commercial use, in teaching languages, and in all instances where there is but one listener, tubes are used in place of the horn.

Table 23 is a detailed summary for this industry at the census of 1905.

[1] Twelfth Census, Manufactures, Part IV, page 181.

TABLE 23.—PHONOGRAPHS AND GRAPHOPHONES—DETAILED SUMMARY, BY STATES: 1905.

	United States.	New Jersey.	All other states.[1]

AUTOMOBILES

AUTOMOBILES.

By GEORGE E. OLLER.

In five years the manufacture of automobiles in the United States has grown from an industry so unimportant that it was not reported separately at the census of 1900 to one with products valued at $26,645,064 at the census of 1905, which covered the calendar year 1904. This remarkable growth is not, like that of the bicycle, based on a fad, and so liable to as sudden a decline. Unlike the bicycle, the automobile is not essentially a new vehicle, but merely a carriage or truck with a new means of propulsion, possessing many advantages over a vehicle drawn by horses. As a means of amusement its popularity may fluctuate or decline, but its practical value has been so thoroughly demonstrated that its use will doubtless become more general each succeeding year, until it is displaced by some vehicle as much its superior as the automobile is the superior of the horse and wagon.

In this report the industry is first taken up statistically, and most of this statistical discussion has to do only with the figures for establishments manufacturing automobiles as a principal product. At the end of this presentation there are briefly taken up, in the order named, automobiles as a minor product; the closely allied industries, "automobile bodies and parts" and "rubber and elastic goods;" and exports and imports of automobiles. A detailed summary of the industry closes the report. Under the historical and descriptive section which follows the statistical discussion the development of the modern automobile, motors, frame, wheels, and body are taken up in the order named.

At the census of 1905, for the first time, the manufacture of automobiles was returned as a separate industry. At preceding censuses the statistics for the industry were included under those for carriages and wagons. However, the figures for 1900 of establishments engaged exclusively in the manufacture of automobiles, or with a preponderating automobile product, have been separated from the reports for the carriage and wagon industry, and are presented in Tables 1 and 2 for purposes of comparison.

Table 1 is a comparative summary of the statistics of the industry for 1900 and 1905.

TABLE 1.—*Comparative summary, with per cent of increase: 1905 and 1900.*

	CENSUS.		Per cent of increase.
	1905 [1]	1900	
Number of establishments	121	57	112.3
Capital	$20,555,247	$5,768,857	256.3
Salaried officials, clerks, etc	954	268	256.0
Salaries	$1,076,425	$294,770	265.2
Wage-earners, average number	10,239	2,241	356.9
Total wages	$6,178,950	$1,320,658	367.9
Men 16 years and over	10,196	2,231	357.0
Wages	$6,167,345	$1,317,715	368.0
Women 16 years and over	11	4	175.0
Wages	$3,689	$977	262.7
Children under 16 years	32	6	433.3
Wages	$7,916	$1,966	302.6
Miscellaneous expenses	$3,946,369	$281,129	1,303.8
Cost of materials used	$11,658,138	$1,804,287	546.1
Value of products	$26,645,064	$4,748,011	461.2

[1] Exclusive of the statistics of establishments engaged primarily in the manufacture of other products and which manufactured automobiles to the value of $879,205.

At the census of 1905 compared with that of 1900 the number of establishments increased 64; the capital, $14,786,390; the number of salaried officials, 686; the average number of wage-earners, 7,998; the cost of materials, $9,853,851; and the total value of products, $21,897,053.

The relatively small increase in number of establishments is due to the fact that the majority reported in 1900 were engaged largely in experimental work, with little capital invested, and employing few workmen. Growth has been along the line of extending the capacity of the old plants, or abandoning them for new and much larger ones, rather than in increasing the number of establishments.

Table 2 shows the items of miscellaneous expenses for 1900 and 1905.

TABLE 2.—*Miscellaneous expenses: 1905 and 1900.*

	1905	1900
Total	$3,946,369	$281,129
Rent of works	88,497	40,133
Taxes	77,625	10,228
Sundries and rent of offices	2,745,601	226,548
Contract work	1,034,646	4,220

Although the extension of the industry has largely added to the amount expended for contract work, the

largest part of the increase in miscellaneous expenses is due to the cost of advertising, outside office expenses, etc.

The relatively small increase in rent of works is due to the fact that many companies are now housed in new, commodious quarters of their own, whereas in 1900 they occupied small rented quarters.

Table 3 is a comparative summary of the statistics for the manufacture of automobiles, by states, for 1900 and 1905.

[1] No establishments reported in 1900.
[2] Included in "all other states" in 1900.
[3] No establishments reported in 1905.
[4] Includes establishments distributed as follows: Kansas, 1; Maine, 1; Minnesota, 1; Missouri, 1; New Hampshire, 1; Rhode Island, 2.
[5] Includes establishments distributed as follows: Connecticut, 2; Indiana, 1; Maine, 2; Missouri, 1; New Hampshire, 1; Wisconsin, 1.
[6] Not reported separately.

Table 3 shows that the manufacture of automobiles was carried on in 13 states in 1900, and in 17 in 1905. At the census of 1905 Michigan, with 22 establishments, ranked first. New York stood second, with 21, and Ohio third, with 14. Massachusetts, with 11 establishments; Illinois and Indiana, with 8 each; Connecticut, with 7; California, Pennsylvania, and Wisconsin, with 6 each; and New Jersey, with 5, followed in the order named.

Michigan, from which state no establishments were reported in 1900, held first rank in capital invested in 1905, the amount being $3,765,240. Connecticut, with $3,712,922, dropped from first place in 1900 to second in 1905. Ohio, with an increase of $3,475,662, more than fiftyfold, advanced from eighth rank to third; Massachusetts, with an increase of $1,148,345, from fifth to fourth; and Pennsylvania, with an increase of $1,155,863, nearly fourfold, from sixth to fifth. Wisconsin, with $1,240,006, and Indiana, with $1,140,509, both of which reported but 1 establishment in 1900, ranked sixth and seventh, respectively, in 1905. With the enormous general increase in the industry, it is surprising to note the following decreases: Illinois fell from second to eighth place, reporting a decrease of $596,358, or 61.2 per cent; and New Jersey, from third to ninth place, with a decrease of $452,239, or 59.3 per cent. Maryland reported $81,600 capital in 1900 and none at all in 1905. In 1900 Connecticut was the only state that reported a total capital in excess of $1,000,000, while there were 8 states in this class in 1905.

From Table 3 it is evident that the average capital per establishment increased materially between 1900 and 1905. For the entire country the advance was from $101,208 in 1900 to $169,878 in 1905, an increase of $68,670, or 67.9 per cent.

The number of wage-earners increased from 2,241 in 1900 to 10,239 in 1905. At the census of 1900 Connecticut ranked first both in number of wage-earners and total wages paid. In number of wage-earners Illinois and Massachusetts followed, each having 303. In wages paid Illinois stood second, with $217,603, and Massachusetts third, with $188,098. New York stood fourth both in number of wage-earners and in wages paid, and New Jersey fifth. These 5 states reported a total of 1,990 wage-earners, receiving $1,168,331 in wages, 88.8 and 88.5 per cent, respectively, of the totals for the country.

In number of wage-earners in 1905 Ohio stood first, with 2,277, an increase of 2,191. Michigan followed, with 2,123. New York, with 1,624, an increase of 1,336, advanced from fourth to third in rank. Connecticut, with 1,065, fell from first to fourth place. Massachusetts, though reporting an increase of 649, fell from second to fifth place. Indiana, Pennsylvania, and Wisconsin followed in the order named. In amount of wages paid in 1905 the states ranked in the same order with a single exception, New York exchanging places with Michigan.

The inconsiderable number of women and children employed is noteworthy. This is due to the fact that the labor requires physical strength and a high degree of mechanical skill. In 1900 only 4 women were employed in the entire United States, 3 of whom were reported by New York. In 1905 the number had increased to only 11. In 1900 only 6 children were employed, and in 1905 but 32.

From Table 3 it will be observed that the relation of the cost of materials to the value of product is practically constant, at least to the extent that the states occupy the same rank, whether arranged according to the cost of materials or according to value of product. This is true for both 1900 and 1905. At the census of 1905 Michigan had advanced to first rank in these two respects. Ohio had risen from sixth to second place, with an increase of $2,238,307 in cost of materials, and an increase of $5,643,563 in value of products. New York advanced from fifth to third place, with an increase of $1,591,594 in cost of materials and $3,336,045 in value of products. Connecticut fell from first to fourth place, though showing an increase of $464,800 in cost of materials and $752,492 in value of products; and Massachusetts from second to fifth, though showing an increase of $740,843 in cost of materials and $1,391,058 in value of products. Wisconsin occupied sixth place in 1905 and Indiana seventh.

In an industry characterized by such marked increases, the decreases reported in nearly every item for the 3 states, Illinois, Maryland, and New Jersey, are notable. The largely experimental stage of the industry and local conditions, such as the removal of factories, are responsible for the decreases.

In 1900 "all other products" included for the most part horse-drawn vehicles manufactured in connection with automobiles, while at the census of 1905 the item represented entirely gas engines, batteries, parts, and finishings, manufactured in excess of the number required for the automobiles turned out. Comparison is therefore impracticable. It is of interest, however, to note the gradual change in certain establishments to meet the new conditions. The change in the character of the "all other products" indicates the abandonment in certain plants of the manufacture of horse-drawn vehicles in favor of the automobile. This item for 1905 shows the extent to which the manufacture of parts overreached the production of the finished automobile.

The amount received for custom work and repairing increased from $73,824 in 1900 to $851,053 at the census of 1905. These amounts represent repair work almost exclusively, and show the extent to which the manufactories are called upon to do this class of work, which is largely on vehicles of their own make. This

does not represent the full extent of the repairing, however, as much of this class of work is done at the local garage in which the machine is housed.

At the census of 1900 only the total number and value of automobiles were reported, regardless of the kind of power used. For the entire United States there were reported 3,723, valued at $4,548,108, an average value of $1,222. Of the various states, Massachusetts produced the greatest number of vehicles, the average value being $669. Connecticut ranked second in the number turned out, the average value being $2,114. Illinois ranked third, with an average value of $1,133; New York, fourth, with an average value of $720; and New Jersey, fifth, with an average value of $1,988.

At the census of 1905 21,692 automobiles were manufactured, valued at $23,751,234, having an average value of $1,095. Of this number, 18,699, or 86.2 per cent, were propelled by gasoline; 1,425, or 6.6 per cent, by electricity; and 1,568, or 7.2 per cent, by steam. The average prices per vehicle were $1,046 for the gasoline, $1,752 for the electric, and $1,077 for the steam. Michigan held to first rank in respect to the number turned out. Only one-tenth of 1 per cent were electric and the remainder gasoline. The total average price was $718. Ohio advanced from sixth place in 1900 to second in 1905, with an average value of $1,851 at the later census. Of this state's output, 64.5 per cent were gasoline; 7.1 per cent electric; and 28.4 per cent steam. Wisconsin ranked third with 2,390 vehicles, only 2 of which were electric and the rest gasoline. The average value was only $777, owing to the fact that they were mostly runabouts. Massachusetts, first in 1900 in the number of machines turned out, dropped to fourth place in 1905. Of the total, 25.4 per cent were steam and the remainder gasoline. The total average value was $868. New York fell from fourth to fifth place. Of the 1,808 vehicles made in the year covered by the census, 82.7 per cent were gasoline; 17 per cent electric; and only three-tenths of 1 per cent steam. However, on account of the large average value of all machines, $1,699, New York ranked third in value of product. These 5 states taking precedence as to the number of automobiles manufactured, reported in 1905 a total of 18,496 vehicles, or 85.3 per cent of the total for the country, having a value of $18,730,894, or 78.9 per cent of the total value of all machines manufactured in the United States.

Table 4 shows the chief classes of automobiles manufactured, with their number and value, and distribution, by kind of power used.

TABLE 4.—NUMBER AND VALUE OF AUTOMOBILES, BY CLASS AND KIND OF POWER USED: 1905.

All other varieties	1,007	1,127,156	675	271,700	330	847,456	2	8,000

[1] Does not include 729 runabouts, valued at $433,596, and 210 touring cars, valued at $204,934, manufactured as a minor product in establishments principally engaged in other lines of manufacture. In addition 199 automobiles, valued at $235,675, manufactured in carriage and wagon factories, are not included in this table, because the classes and power were not reported.

Table 4 shows that 12,131, or 55.9 per cent, of the total number of automobiles manufactured in the United States were runabouts. Of these, 90.7 per cent were gasoline; 3.7 per cent electric; and 5.6 per cent, steam. Less in number, though greater in aggregate value, were the touring cars, constituting 33.3 per cent of the total vehicles turned out. Of this class, 89.3 per cent were propelled by gasoline, 10.2 per cent by steam, and only five-tenths of 1 per cent by electricity. Stanhopes were fourth in point of number, of which 39.6 per cent were gasoline, 40.2 per cent electric, and 20.2 per cent steam. Light and heavy delivery wagons ranked next, of which 47.4 per cent were gasoline, 52.1 per cent electric, and five-tenths of 1 per cent steam. The figures for delivery wagons indicate that electricity is the preferred motive power for the heaviest vehicles.

Under "other varieties" are classed broughams, landaulets, omnibuses, sight-seeing coaches, buckboards, etc.

Michigan produced 6,432 runabouts, having an average value of $631. These runabouts constituted 70.5 per cent of all automobiles manufactured in the state and 53 per cent of the total runabouts manufactured in the United States. All but 11 were propelled by gasoline. Michigan also ranked first in touring cars, report-

ing 2,561, or 35.5 per cent, of all of this class of automobiles manufactured in the country. Their average value was $938.

Ohio produced 186 runabouts, valued at an average of $670; 2,521 touring cars, valued at an average of $1,971; and 100 electric stanhopes, valued at an average of $1,000. This state turned out 34.9 per cent of all the touring cars made in the country. Michigan and Ohio together turned out 70.4 per cent of all such vehicles manufactured in the United States.

Of the 2,390 vehicles made in Wisconsin, 2,358 were runabouts, averaging $775 in value. Among the automobiles manufactured in Massachusetts there were 1,153 runabouts, valued at $708 apiece; 361 touring cars, valued at $1,918 apiece; 105 surreys, valued at $1,046 apiece; and 73 light delivery wagons, valued at $2,255 apiece. The greater number of machines manufactured in New York consisted of runabouts, having an average value of $1,075. The 397 touring cars turned out had an average value of $2,509.

Table 5 gives the average value of the different classes and kinds of automobiles manufactured.

TABLE 5.—*Average value of automobiles, by class and kind of power used: 1905.*

CLASS.	All kinds of power.	Gasoline.	Electric.	Steam.
Aggregate	$1,095	$1,046	$1,752	$1,077
Touring car	1,632	1,641	1,411	1,561

Delivery, light	1,815	1,542	2,161	2,000
Surrey	1,040	831	1,271	1,419
Victoria	1,178	.....	1,178	.....
Phaeton	1,417	1,422	1,200	.....
Doctor's wagon or car	873	500	880	.....
Station wagon or car	1,215	.....	1,215	.....
All other varieties	1,119	403	2,568	4,000

A noticeable feature of Table 5 is the variation indicated in the average values of the same class of machine when equipped with different kinds of propelling power. Where the power is different in vehicles of the same class, the structure is entirely changed.

The average values given are based on the prices at the factory and in no case represent the average selling prices to the consumer. In the 5 leading states the average value of runabouts varied as follows: Michigan, $631; Ohio, $670; Wisconsin, $775; Massachusetts, $708; and New York, $1,075. The average value of touring cars varied still more: Michigan, $938; Ohio, $1,971; Massachusetts, $1,918; and New York, $2,509.

In order to show the remarkable changes in the relative positions of the leading states in this industry, Table 6 is presented, showing their rank with respect to the principal items of inquiry for 1900 and 1905.

The states selected for this table are the 7 leading states in value of products in 1905. The same rank in any item of inquiry was retained at the two censuses in only five cases. Michigan made the most marked advance, from no standing at all in the industry in 1900 to first in most respects at the census of 1905. Connecticut, first in most respects in 1900, dropped from one to three points in all items of inquiry. Ohio advanced from two to five points in every item. New York retained about the same relative position at both censuses, having varied none at all in respect to two of the six items and not more than two points in any of the others. In the amount of capital the rank of Massachusetts remained unchanged, but this state fell from two to three points in each of the other items. Indiana advanced from one to four points in every item. In the number of establishments the rank of Wisconsin remained the same, but this state advanced from two to five points in each of the other items.

TABLE 6.—RANK OF LEADING STATES WITH RESPECT TO PRINCIPAL ITEMS OF INQUIRY: 1905 AND 1900.

STATE.	NUMBER OF ESTABLISHMENTS.		CAPITAL.		WAGE-EARNERS AND WAGES.				COST OF MATERIALS USED.		VALUE OF PRODUCTS.	
					Average number.		Wages.					
	1905	1900	1905	1900	1905	1900	1905	1900	1905	1900	1905	1900

Indiana	5	7	8	11	6	7	6	10	7	9	7	9

[1] No establishments reported in 1900.

Table 7 presents statistics of the manufacture of automobiles at the census of 1905 in cities having in 1900 a population of over 20,000.

TABLE 7.—SUMMARY FOR CITIES HAVING A POPULATION IN 1900 OF AT LEAST 20,000: 1905.

CITY.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
			Number.	Salaries.	Average number.	Wages.			
Total	86	$16,340,573	739	$859,302	8,081	$4,961,205	$3,399,442	$9,044,119	$21,075,073
Buffalo, N. Y.	5	790,853	53	70,859	625	389,505	179,562	579,604	1,385,509
Chicago, Ill.	7	376,886	15	26,180	145	99,433	61,591	103,740	324,710
Cleveland, Ohio	7	2,653,837	127	175,749	1,505	868,399	589,262	1,880,108	4,256,979
Detroit, Mich.	12	2,982,949	106	132,006	1,564	733,012	1,287,160	2,199,277	5,382,212
Indianapolis, Ind.	4	810,160	62	56,177	447	277,844	134,920	553,973	797,652
Kalamazoo, Mich.	3	96,471	9	7,828	48	28,019	10,874	29,564	72,959
New York, N. Y.	6	1,357,064	54	63,086	430	418,581	242,339	672,080	1,186,452
Reading, Pa.	3	367,694	19	11,968	164	91,428	19,948	132,617	269,464
All other cities[1]	39	6,904,659	294	315,449	3,153	2,054,984	863,786	2,893,156	7,399,136

[1] Includes establishments distributed as follows: Albany, N. Y., 1; Boston, Mass., 1; Bridgeport, Conn., 1; Cambridge, Mass., 1; Grand Rapids, Mich., 1; Hartford, Conn., 1; Hoboken, N. J., 1; Holyoke, Mass., 1; Jackson, Mich., 1; Los Angeles, Cal., 1; Milwaukee, Wis., 2; Minneapolis, Minn., 1; Newark, N. J., 1; New Britain, Conn., 1; New Haven, Conn., 1; Oshkosh, Wis., 1; Passaic, N. J., 1; Philadelphia, Pa., 1; Pittsburg, Pa., 1; Poughkeepsie, N. Y., 1; Providence, R. I., 2; Racine, Wis., 1; Rochester, N. Y., 1; St. Louis, Mo., 1; San Francisco, Cal., 2; San Jose, Cal., 2; Springfield, Mass., 1; Springfield, Ohio, 1; Syracuse, N. Y., 1; Taunton, Mass., 1; Toledo, Ohio, 2; Topeka, Kans., 1; Utica, N. Y., 1, Waltham, Mass., 1.

Of the total number of establishments in the United States Table 7 shows that 86, or 71.1 per cent, were located in cities of over 20,000 population. Of the totals for the country the capital invested in these establishments was 79.5 per cent; the number of salaried officials, etc., 77.5 per cent; the salaries paid, 79.8 per cent; the number of wage-earners, 78.9 per cent; the wages paid, 80.3 per cent; miscellaneous expenses, 85.9 per cent; cost of materials used, 77.6 per cent; and the value of products, 79.1 per cent. The average capital, cost of materials, and value of products, for the establishments located in the cities included in this table was $190,007, $105,164, and $245,059, respectively, as compared with $120,419, $74,686, and $159,143 for all automobile works located in the smaller cities, villages, and rural districts.

The prominence which Michigan holds in this industry is due, in large measure, to the establishments located in Detroit. The capital invested in this city alone was 14.5 per cent of the total for the United States; and the value of products 20.2 per cent of the total. The average capital invested per establishment in Detroit was $248,579, and the average value of products $448,518, compared with $379,120 and $608,140, the respective averages for establishments located in Cleveland, the second city in rank as to value of products. These two cities together were credited with more than one-third the total value of products for the entire country.

Contrasted with the compactness of the industry shown in the four leading centers—Detroit, Cleveland, Buffalo, and New York—is its wide dispersion among the 34 cities included in "all other cities." These scattered plants were located in 13 different states, as follows: Six plants in 6 different cities of Massachusetts; 5 in a like number of cities of New York; 5 in 3 cities of California; 4 in 4 cities of Connecticut; 4 in 3 cities of Wisconsin; 3 in 3 cities of New Jersey; 3 in 2 cities of Ohio; 2 in 2 cities in each of the states of Michigan and Pennsylvania; 2 in 1 city of Rhode Island; and 1 in each of the states of Kansas, Minnesota, and Missouri.

Table 8 is a comparative summary of the motive power used in 1900 and 1905.

TABLE 8.—*Power—comparative summary: 1905 and 1900.*

	1905	1900
Number of establishments reporting	113	51
Total horsepower	10,484	3,601
Owned:		
Engines—		
Steam—		
Number	53	33
Horsepower	5,565	2,610
Gas or gasoline—		
Number	59	13
Horsepower	1,149	130
Water wheels—		
Number	1	2
Horsepower	40	75
Electric motors—		
Number	96	32
Horsepower	2,860	437
Rented:		
Electric motors—		
Number	64	13
Horsepower	792	164
Other kind, horsepower	78	185
Furnished to other establishments, horsepower	25	7

A noteworthy fact shown by Table 8 is the marked increase in the average power used per establishment in 1905 over 1900. The 113 plants reporting in 1905 used an average of 92.8 horsepower per establishment, an increase of 22.2 horsepower over the average for 1900. In addition to the increased horsepower used, there was scarcely an establishment which had been in existence for three or four years that had not been enlarged.

AUTOMOBILES AS A MINOR PRODUCT.

The foregoing statistics pertain entirely to establishments engaged primarily in the production of au-

tomobiles, and therefore do not include 47 establishments engaged primarily in the manufacture of other products, but which during the census year 1905 turned out 1,138 automobiles, valued at $879,205. This amount has been included in the value of products of the several industries to which these plants belong. In 24 establishments classified under "carriages and wagons," 199 automobiles, valued at $235,675, were produced. In the industry "bicycles and tricycles" 6 establishments turned out 470 automobiles, valued at $314,554. Of these, 360 were runabouts and 110 touring cars. In "foundry and machine shop products" 13 establishments turned out 228 automobiles, valued at $190,700 and made up of 192 runabouts and 36 touring cars. Four establishments, 2 classified as "shipbuilding, wooden, including boat building," 1 as "sewing machines and attachments," and 1 as "carriage and wagon materials," reported 241 automobiles, valued at $138,276, manufactured as a minor product. Of these machines, 177 were runabouts and 64 touring cars. All these automobiles were propelled by gasoline, with the possible exception of those manufactured in carriage and wagon factories, for which the power was not reported.

ALLIED INDUSTRIES.

Automobile bodies and parts.—In considering the increase of the industry, it must be borne in mind that the entire work of manufacturing was not performed at the automobile factory. Certain parts were manufactured in establishments making a specialty of the component parts of the automobile, such as bodies, wheels, motors, lamps, and various articles of hardware. While some of the larger plants turn out all the parts, the smaller establishments, and by far the greater number, do not, but purchase more or less material in fully or partially manufactured form. In fact, there is a strong tendency in this direction, especially in the separate manufacture of the body of the automobile, as distinguished from the chassis or running gear. The Census classification for such establishments is "automobile bodies and parts." Although they enter into the statistics of the automobile industry proper only to the extent that their products constitute a portion of the cost of materials and miscellaneous expenses, they are really an integral part of that industry. In 1900 there was no separate classification of "automobile bodies and parts," therefore the general statistics for this industry are available only for the census of 1905.

A combination of the statistics for automobiles given in Table 1, and the figures given above for automobile bodies and parts, is exhibited in Table 9.

TABLE 9.—*Summary—automobiles and automobile bodies and parts: 1905.*

	Total.	Automobiles.	Automobile bodies and parts.
Number of establishments	178	121	57
Capital	$23,083,860	$20,555,247	$2,528,613
Salaried officials, clerks, etc	1,181	954	227
Salaries	$1,257,259	$1,076,425	$180,834
Average number of wage-earners	12,049	10,239	1,810
Total wages	$7,156,868	$6,173,260	$983,608
Miscellaneous expenses	$4,266,154	$3,946,369	$319,785
Cost of materials used	$13,151,365	$11,658,138	$1,493,227
Value of products	$30,033,536	$26,645,064	$3,388,472

Rubber and elastic goods.—Another industry which enters largely into automobile construction is the manufacture of rubber and elastic goods. A leading product of this industry is rubber tires, which form a very necessary element in automobile construction. The magnitude of the "rubber and elastic goods" industry in the United States, as well as its growth since 1900, is shown in Table 10.

TABLE 10.—*Rubber and elastic goods—comparative summary: 1905 and 1900.*

	1905	1900
Number of establishments	224	261
Capital invested	$46,297,537	$39,302,353
Average number of wage-earners	21,184	20,404
Total wages	$9,412,368	$8,081,803
Miscellaneous expenses	$6,516,272	$2,805,200
Cost of materials used	$38,912,226	$33,482,314
Value of products	$62,995,909	$52,621,830

Table 10 shows that during the five-year period there was an increase of $10,374,079 in the value of products of the rubber industry. A large part of this increase was caused not only by the enormous quantity of rubber used in the equipment of automobiles, but in the manufacture of various articles made necessary by their extensive use. Of the total increase, $8,633,499, or 83.2 per cent, was reported by the single state of Ohio. Some establishments there located have doubled their product between 1900 and 1905, which is largely, and in some cases entirely, through the increasing demand for automobile tires.

IMPORTS AND EXPORTS.

Table 11 shows the value of exports of automobiles and automobile parts from the United States to foreign countries for each year since they have been separately reported.

TABLE 11.—*Value of exports of automobiles and automobile parts, for years ending June 30: 1902 to 1905.*[1]

EXPORTED TO—	1905	1904	1903	1902
Aggregate	$2,481,243	$1,895,605	$1,207,065	$948,528

[1] "Commerce and Navigation of the United States," Bureau of Statistics, Department of Commerce and Labor.

Table 11 shows the growing favor with which American-made automobiles are being received in foreign countries. The figures are also ample evidence that American manufacturers are fully alive to the advantage of extending their trade abroad. The number of cars exported is not available.

Europe has afforded the best market, though its percentage of the total purchases appears to be decreasing. During the years 1902 to 1905 this percentage was 83.9, 70.7, 53.8, and 57.6, respectively. However, the value of the exports to this grand division almost doubled in the three years. North America, whose purchases increased from $77,801 in 1902 to $682,609 in 1905, nearly eightfold, ranked second as a market for this class of American manufactures; and was followed by Asia, which showed an increase from $22,832 in 1902 to $120,264 in 1905, more than fourfold. In the three years Oceania increased its purchases from $23,797 to $101,464, or 326.4 per cent; South America, from $15,353 to $81,368, or 430 per cent; and Africa, from $12,637 to $67,127, or 431.2 per cent.

The great number of countries into which the American-made machine finds its way, some themselves foremost in the automobile industry, and some among the most remote in the world, will be a source of surprise to many readers.

Of the European countries, by far the greatest exportation has been to the United Kingdom, although during the three years there has been a small decrease of $64,152, or 9.6 per cent. Of the North American countries, the greatest exportation was to the Dominion of Canada, the purchases of which showed a gain of $403,986, or over tenfold, during the three years. Argentina and Peru in South America; British South Africa; and British India, Japan, and the Chinese Empire in Asia proved to be the best markets in their respective grand divisions.

Table 12, compiled from the Annual Reports of the Bureau of Statistics, Department of Commerce and Labor, shows the value of imports of automobiles and automobile parts for the fiscal years ending June 30, 1901 to 1905, together with the number, total value, and average value of the automobiles.

TABLE 12.—*Automobiles and automobile parts imported and entered for consumption during the fiscal years ending June 30: 1901 to 1905.*

YEAR.	Aggregate value.	AUTOMOBILES.			Automobile parts, value.
		Number.	Total value.	Average value.	
1901	$47,471	26	$43,126	$1,658.59	$4,345
1902	550,199	224	530,876	2,369.98	19,323
1903	1,009,001	317	963,998	3,041.00	45,003
1904	1,446,303	423	1,294,160	3,059.48	152,143
1905	2,433,507	653	2,297,104	3,517.77	136,403

Prior to the beginning of the fiscal year 1901 imports of automobiles were not enumerated separately. Since that time there has been a remarkable increase. This constant gain is due largely to the fact that the

majority of the automobiles imported are heavy, high-power touring cars, with multiple cylinder motors, in the construction of which foreign makers have gained preeminence. American designers have heretofore directed their efforts mainly toward the production of a light car equipped with horizontal motors, and in this type they have attained a higher efficiency than foreign makers. The work of the American and of the foreign manufacturers has thus been largely along different lines. However, the great advance being made by Americans in the manufacture of the touring car along the lines laid down by foreign makers indicates that conditions will assume a different aspect in the near future.

Not only the number and value of imports of automobiles have increased rapidly from year to year, but also the average value per machine has advanced steadily from $1,658.59 in 1901 to $3,517.77 in 1905, an increase of $1,859.18, or 112.1 per cent. This increase is not due to an advance in the price of imported vehicles, but to the importation of a higher grade of machines.

STATISTICAL SUMMARY.

Detailed statistics for the industry, as reported at the census of 1905, are shown in Table 13. This table presents totals for each of the 11 states which have three establishments or more engaged in manufacturing automobiles as a principal product, and combined totals for the 6 states having each less than 3 establishments. The components of the capital are shown, viz, amount invested in land; buildings; machinery, tools, and implements; and cash on hand and sundries. The salaried employees are classified into officers of corporations, and general superintendents, managers, clerks, etc., and wage-earners—men, women, and children—with the different amounts paid each class. The average number of men wage-earners employed during each month of the year is also given. Miscellaneous expenses, the cost of materials used, the value of products, and the kind and amount of power used are shown in detail.

HISTORICAL AND DESCRIPTIVE.

The modern automobile.—The early experimenters in motor vehicles were hampered by the lack of engines which used a fuel less heavy and bulky than coal. Light vehicle motors were made possible by the successful production of liquid or volatile fuels and the invention and perfection of the gas engine. The motive power in these gas or gasoline engines is furnished by a succession of explosions which take place within the cylinder itself, thereby doing away with the cumbersome boiler and furnace.

In 1886 it fell to the lot of two Germans, Gottlieb Daimler and Carl Benz, working independently, to apply the gas engine to road vehicles successfully. This revolutionized motor vehicle construction and occasioned its first great impetus. Daimler, who was manager of the Otto Gas Engine Works at Deutz, fitted his small air-cooled motor to a bicycle by placing it vertically between the front and rear wheels, the rear wheel being driven by means of a belt. In 1889 he constructed a two-cylinder engine, which attracted the attention of Messrs. Panhard and Levassor, of Paris, who acquired the necessary rights and immediately began the construction of the essentially modern motor car, the first of which was brought out in 1891.

Carl Benz first applied his single horizontal cylinder, water-jacketed engine to a three-wheel carriage. It was placed over the rear axle and drove a vertical crank shaft, thus giving the fly wheel a horizontal position. This arrangement insured stability in the steering of the car. The crank shaft was connected by bevel gearing to a short horizontal shaft, which was in turn coupled to a countershaft by a belt. The ends of this countershaft were connected to the road wheels by means of chains. Benz's engine was first worked on the two-stroke cycle, but in the subsequent development of the machine, in which he was assisted by Roger, of Paris, the Otto four-stroke cycle was used.

However, it must be remembered that during this earliest period in the evolution of the modern automobile the steam engine was advancing in efficiency and light construction to a degree equal to or greater than the gasoline engine. In Europe the most notable achievements along this line were those of Leon Serpollet, a Frenchman, who applied to road vehicles his instantaneous or "flash" generator, invented in 1889. The principle of this great invention consists in generating steam instantaneously by pumping water through flattened tubes of a very narrow section kept at a red heat by the furnace. The fuel used is vaporized oil.

The earliest attempts by American inventors to build horseless carriages were confined to steam motors. The omnibus built in 1878 by a Mr. Fawcett, of Pittsburg, employed a Brayton motor of unknown design. During the eighties a Mr. Copeland brought out a bicycle equipped with a steam motor, followed by two tricycles similarly equipped, which were the predecessors of the light steam vehicles. However, Copeland had to abandon his experiments through lack of capital.

The distinction of early experiments in this line is also claimed by a citizen of the state of Michigan in the person of Mr. R. E. Olds, who in 1886 began the construction of a horseless carriage. This vehicle, which was not completed until the following year, 1887,

was first fitted with a steam engine which was geared to the rear axle. The boiler was of the porcupine type and gasoline was used as the fuel. Later, this machine was remodeled, using a flash boiler, that is, the steam was generated only as required by the engines. In 1893 Mr. Olds began building gasoline motors for horseless carriages which, since their perfection in 1895, have proved practical and successful.

In 1886 Charles E. Duryea decided that the gasoline engine was best fitted to propel the horseless carriage. It was, however, not until 1892 that assisted by his brother, J. F. Duryea, he completed his first automobile. This machine proved to be decidedly underpowered and built of too light materials. Their next car, finished in 1893, embodied all the essential features of the modern automobile and was a success. The Duryea Motor Wagon Company was organized, and the 13 automobiles finished in the summer of 1896 were the first manufactured for sale in the United States. The price of these vehicles, $1,500, was considered very high for an untried substitute for the horse and carriage and prevented the immediate acceptance of the gasoline automobile in America. A large majority of the plants reported for the industry at the census of 1900 commenced operation in 1899, the date of the substantial beginning of the automobile movement in America.

Steam motors.—The principal parts of the steam motor are the boiler and engine. Two types of tubular boilers are used, the water tube and fire tube, according to whether the tubes are to contain fire or water. The Serpollet boiler, used almost universally in European steam vehicles, is of the water-tube variety, while American builders use the fire-tube type to a great extent. The common boiler used in American steam machines is a cylindrical upright steel shell, through which pass vertical copper or steel fire tubes, from 300 to 350 in number.

The invention of the instantaneous generator, known by the name of the inventor, Leon Serpollet, in 1889, gave the first real impulse to modern steam carriage building. It consisted of a coil of 1½-inch lap-welded steel tubing flattened, in the earliest type, until the bore was of almost capillary width, but later to a width of about one-eighth of an inch. The coil was surrounded by a cast-iron covering to protect the steel from corrosion by heat. The water, upon being injected into the heated tube, was vaporized almost instantly. Two coils connected in series were later used, and finally a train of coils and bent tubing.

The engine used with the Serpollet boiler has four single-acting cylinders arranged in pairs. They may be set either obliquely, so as to make an angle of 45 degrees with each other at the crank shaft, or horizontally on opposite sides of the crank shaft. A countershaft is used, parallel to the rear axle, connected with the crank shaft by chain, and to the driving axle by gearing.

The engine most commonly used on the lighter vehicles by American manufacturers is double-cylindered, double acting, and set vertically. The diameter of the cylinder varies from 2½ to 3 inches, and the stroke from 3 to 3½ inches. The power is transmitted usually direct from the engine shaft to the rear driving axle by chain, but in a few cases the countershaft is used. The fuel used is some form of mineral oil, usually gasoline, or alcohol, which is vaporized by the use of special burners. Compressed air, supplied by either a hand pump or a power pump operated by the moving parts of the engine, affords a pressure for feeding the oil to the burners. Automatic feed pumps, operated by the engine, supply water to the boilers.

Petrol motors.—In 1882 M. Beau de Rochas, a French engineer, patented an internal-combustion engine. The principles of this invention have ever since afforded the basis for designers of this class of engine. The simplest form consists of a single cylinder closed at the top and open at the bottom, within which moves a closely fitting piston, connected by a swinging rod to the crank shaft. A mixture of air and the vaporized spirit is introduced into the cylinder when the piston is at the top, forming a cushion between the fixed top of the cylinder and the movable piston. The mixture is then ignited, causing an explosion. The piston, which is fitted gas tight, is the only thing that can give way, and is driven to the bottom of the cylinder, where its further downward movement is arrested by the crank. The impulse of this explosive stroke is stored in a fly wheel attached to the crank shaft, which is carried round again, driving the piston up.

The mechanism described is the two-stroke cycle, sometimes called the "two-cycle engine." The chief claim for this type of engine is its undoubted simplicity. The absence of valves, gears, cams, and springs makes it cheap to manufacture and repair. Although theoretically it would appear to be adapted to the automobile, since the gain in power over a four-cycle engine of the same size exceeds 60 per cent, it has thus far proved unavailable.

The four-cycle engine, more commonly called the "Otto cycle," from Dr. N. A. Otto, the first to make practical use of it, is now almost universally used for the automobile. In this engine there is only one explosion to four strokes of the piston. These are termed, respectively, the suction stroke, to draw into the cylinder the mixture of air and vaporized spirit; the compression stroke; the explosion stroke, following the ignition of the vapor; and the exhaust stroke, to drive out the gases of combustion. It is estimated that an engine of this character is capable of 1,200 to 1,500 revolutions per minute, while a two-cycle engine

of the same power can make no more than 300 to 350 revolutions. The description given is of a single-cylinder engine. Automobiles are variously equipped with one, two, four, six, and eight cylinder motors. Three-cylinder motors have also been tried but to a very limited extent.

The other main parts of the gasoline motor are the carburetor or vaporizer, in which the liquid hydrocarbon is transformed into vapor, and the ignition apparatus, which produces the spark or hot surface essential to explosion. There are two general types of carburetors—surface carburetors that operate by evaporation, and float-feed carburetors or sprayers. At the present time the surface carburetor is little used, except for motor cycles. There are also several methods of ignition, among which may be mentioned the gas jet and hot tube of the Otto engines, the hot head of the Hornsby-Akroyd motor, the hot wall of the Diesel motor, and the electric spark. The Daimler type of carriage motor still retains the hot-tube ignition, while most other types use the electric spark.

On account of the great heat developed in the cylinder of a gasoline motor some means of cooling sufficiently to avert premature explosion and permit of proper lubrication must be employed. The two systems in general use are the air cooling, limited to engines of small dimensions, and the water cooling.

The early motors were practically all air cooled. American inventors first designed successful air cooling systems. The most successful means at present employed to air-cool cylinders is a rotary fan on the main shaft which creates a forced draft through an air jacket surrounding the cylinder, to the outside surface of which fins or flanges are attached, or a large number of brass pins are secured in holes on the outside of the cylinder's wall. The water cooling system, however, by which a constant circulation of water around the cylinder is maintained through the use of a water jacket, is far more generally used.

Like the steam motor, the gasoline motor transmits its power to a crank shaft from which it is conveyed to the driving shaft by a chain or gearing. The motor is generally started by rotating the crank shaft by a lever attached to one end, although several methods are in use by which the engine is automatically started.

In the United States gasoline has been used almost exclusively for automobile internal-combustion motors, although benzine and alcohol are most used in Germany. A law removing the internal revenue tax on denatured alcohol may open the door for a great advance in the automobile industry in the United States by substituting alcohol for gasoline. The importance of this measure may be realized when it is known that the supply of gasoline is limited, as petroleum yields only 2 per cent of gasoline; whereas the sources from which alcohol can be produced are inexhaustible. Alcohol is better and safer than gasoline and also free from unpleasant odors. A recent experiment with a six-cylinder car demonstrated that with the same amounts of gasoline and alcohol, the former developed 52 horsepower, and the latter 60.

Electric motors.—The electric motor for use on the automobile is in a less advanced state of development than either the steam or gasoline motor. The only practical supply of power is by means of heavy storage batteries carried on the car itself. The full capacity of the average storage battery will not carry an automobile more than 40 or 50 miles. If the electricity gives out at any place other than an electric charging station, the machine is helpless. Electrical engineers are working toward a more satisfactory storage battery, which when perfected will undoubtedly make the electric automobile the ideal type, as the mechanism is the simplest and least liable to get out of order. The most notable extension of the use of electric automobiles has been in the industrial field. During the past five years large numbers of electric drays, trucks, delivery wagons, etc., have been built.

The storage battery for supplying the current, the motor for transforming this current into mechanical power, and the controller for regulating the speed of the motor constitute the principal equipment of the electric automobile. The current passes from the storage battery into the motor or reversed dynamo, which drives the rear wheels through proper gearing. When two motors are used no transmission shaft or gearing is necessary. A number of fairly successful vehicles have been introduced in which a hydrocarbon engine drives a dynamo-electric generator which in turn furnishes current to the storage batteries and motor; in some instances the dynamo, being reversible, is also made to play the part of a motor.

Frame, wheels, and body.—In making the frame the ends sought by the automobile manufacturer are lightness and strength. Steel tubing was formerly considered almost essential to secure this desired combination, but experience has proven that the reduction in weight is more than offset by the greater complexity of structure, the present tendency being toward the use of pressed steel.

The wheels of self-propelled vehicles must possess great strength and elasticity. The automobile requires a wheel about eighteen times as strong as the ordinary horse-drawn vehicle, since it carries a load over twice as heavy at a speed over three times as great. Wire wheels, which sustain a heavier load than wooden wheels in proportion to their weight, were first used, but they will not stand so great a side thrust and have therefore been practically superseded by the modern type of artillery wheel. Strength is gained by using a wheel of much smaller diameter than those used on

45254—MFG 1905—PT 4—08——20

horse-drawn vehicles. Heavy tires are necessary to secure efficient traction and the elasticity needed to counteract the vibration caused by the machinery and the irregular roadways.

The present automobile body is a development of the ordinary carriage body. In the pioneer days of the horseless carriage, makers naturally adopted buggy and carriage bodies, as their attention was devoted almost exclusively to the operation of the engine. As the machinery began to work more satisfactorily it was realized that the carriage body was in the way, and the designer was called upon for a body more suitable for an automobile. As the carriage builder was experienced in body making and best equipped for it, the body is now commonly manufactured in a separate establishment from the running gear. The development of the body has kept pace with that of the running gear. American designers have improved upon their French models until now the best American automobile bodies are unexcelled. The separate manufacture of body and running gear has led to the common custom of purchasing the chassis from the automobile maker and the body from some firm engaged in that particular branch of manufacture.

In the manufacture of automobile bodies hickory and cypress are used to some extent, but ash from Michigan, Wisconsin, Indiana, and Ohio, and poplar from Indian Territory and Georgia find most favor. The ash is used for the frame and the poplar for the panels and the top.

The horsepower of the motors used for commercial and pleasure purposes ranges from about 5 to 100. The remarkable progress made by the automobile as a purely speed machine has been furthered by the various tests of speed and endurance arranged largely as a means of recreation. The racing car, with over 100 horsepower crowded into a vehicle weighing 2,000 pounds, has attained a speed of more than 2 miles a minute on specially prepared and peculiarly suitable roads. Even up steep grades nearly 80 miles an hour has been made. In speed the touring car holds a position next to the racing car, as 60 miles an hour can be covered with ease.

Though not yet perfected, the automobile has become at least reliable. Models and parts are being standardized, thus rendering it possible to replace broken or worn out parts without delay. In the United States many express and transfer companies, department stores, and fire departments have abandoned the horse-drawn vehicle for the automobile. In New Mexico it has supplanted the stage coach between Roswell and Torrance, a distance of 101 miles. It has worked a revolution in Nevada, where the means of local transportation have heretofore been confined to the mule. Liverymen acknowledge the passing of the horse by operating automobiles in connection with their stables. In many of the larger cities the automobile has been introduced for public transportation. Although it is as yet unsuited for general transportation in the field, yet the utility and advisability of the self-propelled vehicle for military purposes have been amply demonstrated. In Germany armored automobiles are being constructed for use in the army.

In the United States the use of automobiles will be limited only by their cost and the condition of the highways. The cost is gradually becoming less and the automobile itself is already felt as a factor in the movement for good roads.[1]

[1] In the preparation of the foregoing historical and descriptive sketch the following authorities have been consulted: The Complete Motorist, Young; The Book of the Automobile, Sloss; Self-Propelled Vehicles, Homans; Petrol Motors and Motor Cars, White; Modern Steam Road Wagons, Norris; various publications of The Motor Way; article "Automobiles" in International Encyclopedia.

TABLE 13.—AUTOMOBILES—DETAILED

		United States.	California.	Connecticut.
1	Number of establishments	121	6	7
	Capital:			
2	Total	$20,555,247	$48,802	$3,712,922

BICYCLES AND TRICYCLES

BICYCLES AND TRICYCLES.

By Robert H. Merriam.

The statistics for the 101 establishments that were engaged primarily in manufacturing bicycles and tricycles at the census of 1905, and those for similar establishments for the censuses of 1890 and 1900, are summarized in Table 1.

Table 1.—*Comparative summary, with per cent of increase and decrease: 1890 to 1905.*

	Census.			Per cent of decrease, 1900 to 1905.	Per cent of increase, 1890 to 1900.
	1905[1]	1900	1890		
Number of establishments.	101	312	27	67.6	1,055.6
Capital	$5,883,458	$29,783,659	$2,058,072	80.2	1,347.2
Salaried officials, clerks, etc., number	361	2,034	[2] 128	82.3	1,489.1
Salaries	$350,798	$1,753,235	[2] $123,714	80.0	1,317.2
Wage-earners, average number	3,319	17,525	1,797	81.1	875.2
Total wages	$1,971,403	$8,189,817	$982,014	75.9	734.0
Men 16 years and over	3,298	16,700	1,747	80.3	855.9
Wages	$1,964,940	$7,952,257	$971,539	75.3	718.5
Women 16 years and over	7	517	15	98.6	3,346.7
Wages	$3,481	$175,028	$3,729	98.0	4,593.7
Children under 16 years	14	308	35	95.5	780.0
Wages	$2,982	$62,532	$6,746	95.2	826.9
Miscellaneous expenses	$574,655	$2,252,604	$242,018	74.5	830.8
Cost of materials used	$2,628,146	$16,792,051	$718,848	84.3	2,236.0
Value of products	$5,153,240	$31,915,908	$2,568,326	83.9	1,142.7

[1] Exclusive of the statistics of 13 establishments making bicycles and tricycles, and bicycle parts, but engaged primarily in the manufacture of other products. The value of bicycles and tricycles, and bicycle parts made in such establishments was $575,959.

[2] Includes proprietors and firm members with their salaries; number only reported in 1900 and 1905, but not included in this table.

The most noticeable feature in this industry, as shown by the figures in Table 1, is its rapid growth and decline within fifteen years. The establishments engaged primarily in manufacturing bicycles and tricycles numbered only 27 in 1890, while in 1900 they numbered 312, and at the present census only 101. The decrease is also noticeable in the average number of wage-earners employed, and in the value of the products. The average number of wage-earners decreased from 17,525 in 1900 to 3,319 in 1905, which was only 1,522 more than were employed in 1890, and the value of products decreased from $31,915,908 in 1900 to $5,153,240 in 1905.

Prior to the decade ending in 1880, the manufacture of bicycles was intermittent, and it was not until 1890 that the industry was of sufficient importance in the United States to be reported separately. Up to that time the statistics relating to this industry were included in those for carriages and wagons. During the decade ending in 1900 the progress made was most remarkable, the climax being reached about the middle of that period.

With the general adoption of the pneumatic tire and society's approval of cycling, came the prosperous days of 1894 to 1896. People went cycle mad; the bicycle industry appeared to be an Eldorado, and there was a rush to engage in it. Then followed the decline in popularity, with the resultant dull times and failures among the manufacturers. By 1898, however, the industry was being conducted upon sound economic principles.

When the demand for bicycles decreased some manufacturers turned to the automobile, and many establishments that made only bicycles in 1900 are now devoted primarily to the manufacture of automobiles, while others make them to a greater or less degree in connection with the manufacture of bicycles. As far as reported to this Bureau, the value of automobiles and automobile parts reported at the census of 1905 by establishments devoted primarily to the manufacture of bicycles and tricycles was $345,179.

Production.—Table 2 is a detailed statement, for the United States, of the number and value of the different kinds of products made in all establishments making bicycles and tricycles and bicycle parts during the census years 1900 and 1905.

Table 2.—*Number and value of different kinds of products, including those produced as secondary products: 1905 and 1900.*

All other products	.....	[2] 1,289,806	.....	.....	9,707,663	.....

[1] This item, reported under the classification "bicycle and tricycle repairing," amounted to $13,766,033.

[2] Includes value of automobiles and automobile and bicycle parts, etc.

In addition to the 101 establishments shown in Table 1, there were 13 factories engaged primarily in some other branch of manufacture, which made, during the census year 1905, 25,319 bicycles and tricycles, valued at $551,794; manufactured bicycle parts to the value of $16,540; and did custom and repair work to the value of $7,625. The figures for these 13 establishments are included in Table 2.

The 101 establishments engaged primarily in the manufacture of cycles made 231,667 bicycles and tricycles, valued at $3,591,195; bicycle parts, valued at $933,147; and did custom and repair work to the amount of $288,719. The total value of all products, as shown in Table 2, is $5,729,199. In the item "all other products" is included $345,179, the value of automobiles and automobile parts manufactured by bicycle and tricycle establishments, while the value of chains, spokes, handle bars, saddles, rims, and other parts manufactured make up the greater part of the remaining $944,687.

At the census of 1900 the total number of bicycles reported was 1,182,850, while in 1905 only 252,923 were reported, a decrease of 929,927. It is probable this decrease was much larger than is shown in Table 2, for the reason that in 1900 there were 6,328 establishments classified as bicycle and tricycle repair shops, which undoubtedly manufactured a considerable number of bicycles. As detailed reports were not received from these repair establishments, an estimate of the number of wheels they made would be of little value. The gross value of the product of these shops in 1900, however, was $13,766,033.

The average value of a chain bicycle was $14.59 in 1905 as compared with $18.91 in 1900. This is for a "stripped" wheel at the factory, as the majority of the manufacturers reported stripped and not completely equipped wheels. This explanation also applies to chainless wheels, whose average value at the factory in 1905 was $34.86, while in 1900 it was $45.59. The decrease in price per wheel between the two census periods is but a continuation of the downward trend which first began in 1894, when the price of a complete wheel fell from $150 to $125. In the following year another $25 was deducted, and in spite of the prosperous season of 1895–96 the price continued to fall until it reached the present level of from $35 to $50 for a chain bicycle.

The only kind of machine referred to in Table 2, which shows an increase over 1900, is the motor cycle. In 1900 there were reported 159 motor cycles, valued at $32,950, while at the present census 2,436 are reported, valued at $368,506. The motor cycle had received scant attention during the low ebb in cycling, owing to the general attention being directed toward low-priced machines and the apparently large profits to be made in manufacturing automobiles. Slowly, however, the motor cycle won its way toward recognition, and, one after another, the bicycle establishments took up its manufacture. At the present census 28 establishments are making motor cycles.

Most of the tricycles reported were children's toys, which accounts for the low price.

Table 3 is a comparative summary, by states, of the bicycle and tricycle industry for the censuses of 1890, 1900, and 1905, the table also shows the increases and decreases.

TABLE 3.—*Comparative summary—active establishments, by states, with increase and decrease: 1890 to 1905.*[1]

STATE.	CENSUS.			Decrease, 1900 to 1905.	Increase, 1890 to 1900.

Wisconsin	3	23	.....	20	23

[1] Does not include establishments producing bicycles and tricycles as secondary products.
[2] Increase.
[3] Decrease.

In but 4 states did the industry show an increase in 1905 over 1900, and in 2 of these—Missouri and North Carolina—no establishments were reported in 1900, while in 1905 there were only 2 and 1, respectively. The other states showing an increase were Colorado and Minnesota, in which there were no bicycle and tricycle factories in 1890. California and Maryland had the same number of factories in 1905 as in 1900. Iowa, Kentucky, Maine, Nevada, and New Hampshire each having 1 establishment in 1900 had no plants in 1905. The remaining states which reported establishments in 1900 show a large decrease at the present census. This is particularly noticeable in Connecticut, Illinois, Indiana, Massachusetts, New York, Ohio, Pennsylvania, and Wisconsin.

In 1890 there were only 27 establishments reported which were distributed among 10 states; in 1900, 312 establishments were reported from 20 states, and in 1905 there were 101 factories reported from 17 states. Connecticut, Illinois, Indiana, Massachusetts, Michigan, New Jersey, New York, Ohio, and Pennsylvania have reported active establishments in this industry ever since it was first reported separately. Oregon is the only state named in the table which has reported no active establishments since 1890.

Of the 101 establishments reported at the present census 40 reported in 1900, while 61 are either new

concerns started since 1900, or, in some cases, possibly reorganizations, under different names, of firms active in 1900. As far as ascertained 236 of the bicycle and tricycle plants which reported at the census of 1900 have since then gone out of business, while 36 have retained their names, although they have changed from the manufacture of bicycles and tricycles to some other industry.

Table 4 is a comparative summary, by states, of the figures reported by manufacturers engaged primarily in the production of bicycles and tricycles in 1900 and 1905.

TABLE 4.—COMPARATIVE SUMMARY, BY STATES: 1905 AND 1900.

STATE.	Year.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
				Number.	Salaries.	Average number.	Wages.			
United States	1905	101	$5,883,458	361	$350,798	3,319	$1,971,403	$574,655	$2,628,146	$5,153,240

	[3] 1900	7	831,848	36	57,195	357	165,083	51,008	423,351	779,331

[1] Included in "all other states" in 1905.
[2] Includes establishments distributed as follows: Colorado, 2; Connecticut, 2; Indiana, 2; Maryland, 1; Missouri, 2; North Carolina, 1; Rhode Island, 1.
[3] Includes establishments distributed as follows: Colorado, 1; Iowa, 1; Kentucky, 1; Maine, 1; Maryland, 1; Nevada, 1; New Hampshire, 1.

The most noticeable feature in Table 4 is the decrease in Connecticut, Illinois, Indiana, Massachusetts, New York, Ohio, Pennsylvania, and Wisconsin, that for the last-named state being most prominent. In 1900 each of these states produced bicycles and tricycles valued at over $1,000,000, while in 1905 the product of but 2, Illinois and Ohio, was valued at $1,000,000 or over.

Exports.—The value of bicycles and tricycles and parts thereof exported from the United States each year from 1896 to 1905, inclusive, is shown in Table 5.

TABLE 5.—*Value of exports of bicycles and tricycles, and parts thereof: 1896 to 1905.*[1]

FISCAL YEAR.	Exports.	FISCAL YEAR.	Exports.
1896	$1,898,012	1901	$2,515,804
1897	7,005,323	1902	2,627,572
1898	6,846,529	1903	2,132,629
1899	5,753,880	1904	1,965,026
1900	3,553,149	1905	1,378,428

[1] "Commerce and Navigation of the United States," Bureau of Statistics, Department of Commerce and Labor.

The high tide of bicycle export from the United States was reached in 1897, when the American wheel commanded a market not only in nonmanufacturing countries, but also in the United Kingdom and throughout continental Europe. Excepting a slight increase in 1902 over the previous year, the decline in the export trade has kept pace with the decline in the popularity of the bicycle.

Historical and descriptive.—The history of the bicycle was discussed in the Report on Manufactures, Twelfth Census, Part IV. The history of the manufacture of motor cycles was not dwelt upon at that time but is here introduced.

The first power-driven bicycle produced in the United States was a steam "boneshaker," made and used in 1868 by W. W. Austin, of Winthrop, Mass.[1] This machine, which weighed 90 pounds, is said to have run about 2,000 miles. The engine and boiler were attached to the frame just back of the rider.[2]

[1] The Bicycling World, Vol. XLIII, No. 15, Jan. 10, 1901, page 370.
[2] The Bicycling World, Vol. XLII, No. 7, Nov. 15, 1900, page 141.

During 1884–85 the better known "Copeland steam bicycle" was devised by W. E. and L. D. Copeland, of San Francisco, Cal. The wheel used was of the regular "Star" pattern, and the engine and boiler were planned so as to occupy very little space outside the lines of the machine. The engine proper weighed 1 pound and 12 ounces, including the driving pulley, and the speed was 7 revolutions to 1 of the bicycle. The engine was capable of making 1,000 revolutions per minute. Enough water could be taken into the boiler to last an hour, and the power of the engine was sufficient to drive the 51-inch wheel about 12 miles on a floor, or about 1 mile in eight minutes on the road.[1]

So far as known nothing else in the form of a motor cycle was attempted in this country during the succeeding ten years. During the year 1894–95, when the safety bicycle and pneumatic tires were firmly established, E. J. Pennington, of Cleveland, Ohio, formed the Motor Cycle Company, and advertised extensively both a single and tandem power-driven machine. Kerosene was the fuel used, and it was claimed that 1 gallon would serve for 200 miles. Explosions which drove the machine were caused by electric ignition, the mere pressure of an electric button on the handle bar being sufficient to start or stop the machine and also to regulate the speed. While the contrivance was most ingenious, it was in advance of the times, the public not then being interested in power-driven cycles.[1]

In 1884 Gottlieb Daimler, of Deutz, Germany, produced and patented a small gas engine designed to run at very high speed, so high that the heat generated by it was enough to ignite the charges of gas furnishing the propelling power. This engine Mr. Daimler, in 1886, fitted to a bicycle by placing it vertically between the front and rear wheels, the rear wheel being driven from the engine by means of a belt. Gas was supplied from a carburetor in which an explosive vapor was produced by causing air to enter the liquid from below. This engine proved so satisfactory that Daimler continued work on it, and in 1889 constructed a two-cylinder engine, the piston rods of which were coupled to a single crank.[2]

From 1900 to the present time increased attention has been given to motor cycles, with the result that to-day there are many types upon the market, the majority, if not all, being propelled by a gasoline motor.

Under the report on automobiles in this volume the gasoline motor has been so generally covered that it was not considered necessary to give this subject any further attention in this article.

The detailed statistics for the bicycle and tricycle industry in establishments devoted primarily to their manufacture are presented in Table 6, which gives separate totals for each state in which there are three or more establishments, and groups the statistics for other states so as not to disclose the operations of individual establishments.

CARRIAGES AND WAGONS

CARRIAGES AND WAGONS.

This report embraces establishments conducted on the factory system engaged in the manufacture of every variety of vehicle propelled by animal power for land transportation. It does not include statistics for children's carriages and sleds, bicycles and tricycles, automobiles and other horseless conveyances—except when made as subsidiary products—or for steam and street railroad cars.

The census of 1890 was the first at which establishments engaged in the manufacture of the factory product were segregated from those engaged chiefly in custom and repair work and shown in a separate table, distinct from the totals for the regular classification.

In order that the statistics for the census of 1900 might be strictly comparable with those for 1890 and 1905, a revision was made by which reports for 1,428 establishments, representing capital of $8,311,953 and products of $8,302,686, were eliminated. These reports represented practically all the carriage and wagon custom work and repairing plants, classified under "carriages and wagons" in 1900, and all the plants showing an entire or preponderating product of automobiles. The schedules for the latter were separately compiled to show elsewhere comparative figures for the classification of "automobiles," used for the first time at the census of 1905.

Table 1 is a comparative summary of the statistics for carriages and wagons, factory product, as returned at the censuses of 1890, 1900, and 1905, with percentages of increase.

The figures given for the census of 1905 show a substantial increase over those for 1900, with the single exception of number of establishments; this item is diminished by 1,248, or 20.1 per cent. The decrease is due in part to the fact that it was impossible to eliminate from the statistics for 1900 all the reports for establishments of the character excluded from the factory census of 1905.

The average number of wage-earners increased only 3.4 per cent from 1890 to 1900, while the total wages paid actually decreased 4.8 per cent, but at the census of 1905 these items showed increases of 3.9 per cent and 12 per cent, respectively. The cost of materials used increased 13.9 per cent from 1900 to 1905, and the increase shown in total value of products was 10.7 per cent.

TABLE 1.—*Comparative summary, with per cent of increase: 1890 to 1905.*

	CENSUS.			PER CENT OF INCREASE.	
	1905[1]	1900	1890	1900 to 1905	1890 to 1900
Number of establishments	4,956	6,204	4,572	[2] 20.1	35.7
Capital	$126,320,604	$109,875,885	$93,456,257	15.0	17.6
Salaried officials, clerks, etc., number	5,058	4,003	[3] 6,069	26.4	[2] 34.0
Salaries	$5,239,043	$3,756,915	[3] $5,715,426	39.5	[2] 34.3
Wage-earners, average number	60,722	58,425	56,525	3.9	3.4
Total wages	$30,878,229	$27,578,046	$28,972,401	12.0	[2] 4.8
Men 16 years and over	59,411	57,209	55,403	3.8	3.3
Wages	$30,525,515	$27,264,021	$28,702,169	12.0	[2] 5.0
Women 16 years and over	870	840	615	3.6	36.6
Wages	$266,674	$248,071	$180,195	7.5	37.7
Children under 16 years	441	376	507	17.3	[2] 25.8
Wages	$86,040	$65,954	$90,037	30.5	[2] 26.7
Miscellaneous expenses	$10,182,614	$5,800,687	$5,495,271	75.5	5.6
Cost of materials used	$61,215,228	$53,723,311	$46,022,769	13.9	16.7
Value of products, including amount received for repair work	$125,332,976	$113,234,590	$102,680,341	10.7	10.3

[1] Exclusive of the statistics of 35 establishments engaged primarily in the manufacture of other products. These establishments made carriages and wagons to the value of $612,173.
[2] Decrease.
[3] Includes proprietors and firm members and their salaries; number only reported in 1900 and 1905, but not included in this table.

The industry, by states and territories.—Table 2 is a comparative summary for the industry, by states and territories and geographic divisions, 1900 and 1905.

By far the larger part of the carriage and wagon industry was concentrated in the North Central division. At the census of 1905 this division contained 60 per cent of the total capital invested, 51.5 per cent of the wage-earners, 50.2 per cent of the wages, and 58 per cent of the value of products. Indiana and Illinois were the only states showing important increases.

The North Atlantic division ranked next to the North Central, with 26.3 per cent of the capital for the whole country, 30.9 per cent of the wage-earners, 33.8 per cent of the wages, and 25.6 per cent of the value of products. Of the separate states all reported a general decline except Maine, New York, and Pennsylvania.

TABLE 2.—COMPARATIVE SUMMARY, BY STATES, TERRITORIES, AND GEOGRAPHIC DIVISIONS: 1905 AND 1900.

STATE OR TERRITORY.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products, including amount received for repair work.

[1] Included in "not distributed by states or divisions" in 1905.
[2] Includes establishments distributed as follows: Arizona, 1; Indian Territory, 1; Nevada, 1; North Dakota, 1; Wyoming, 1.
[3] Includes establishments distributed as follows: Indian Territory, 1; Nevada, 2.

The Southern states, though still forming relatively small proportions of the total, showed substantial increases. The two divisions into which they were grouped were nearly equal in importance. The South Atlantic was in the lead with 7.4 per cent of the total value of products against 6.3 per cent for the South Central. The gain in the South Atlantic division was mainly due to the large increase in North Carolina, while more than half the increase in the South Central division was credited to Kentucky.

The figures for the Western division are relatively small, and the substantial gains in the various items are not sufficient to cause any material change in the percentages of the totals compared with 1900. California, Oregon, Washington, Montana, and New Mexico show a gain in value of products, the other states showing losses.

In value of products, Ohio was the leading state at the censuses of both 1900 and 1905. At the later census this value was 12.8 per cent of the total output, as against 13.8 per cent of the total for 1900. Indiana, New York, Michigan, and Illinois came next, in the order named, at both censuses, with 11.2, 10.8, 9.8, and 7.3 per cent, respectively, of the total value in 1900; and 12.2, 10, 9.7, and 7.8 per cent at the census of 1905. Relatively, Indiana and Illinois alone advanced, Michigan about holding its own and New York losing ground.

Five states showed an increase of over $1,000,000 between 1900 and 1905, Indiana, Illinois, North Carolina, Kentucky, and Missouri, in the order named. Wisconsin reported an increase of less than $700,000. Georgia ranked next to the 5 states mentioned with $986,199, or more than double the increase for Ohio, the state first in rank according to total value. The percentages of increase in these states were also nota-

ble—20.3 for Indiana, 18.4 for Illinois, 118.3 for North Carolina, 42.5 for Kentucky, 19.6 for Missouri, and 74.9 for Georgia. Ohio's increase was only 3.1 per cent.

An examination of the figures for wage-earners and wages shows that of the 15 leading states, according to value of products, 4 reported fewer wage-earners at the census of 1905 than in 1900. The states showing these losses were: Iowa, 481, or 30.4 per cent; Massachusetts, 459, or 17.1 per cent; Ohio, 361, or 5.1 per cent; and Michigan, 171, or 3.5 per cent. Of the states showing gains, Indiana reported the largest, 731, or 11.4 per cent, rising from third to first place; Pennsylvania was second with 624, or 12.6 per cent; North Carolina and Georgia were next with 574 and 307, or 71.8 and 38 per cent, respectively.

The industry in cities.—Of the total number of establishments in the United States reported at the census of 1905 as engaged in the manufacture of carriages and wagons, 1,914, or 38.6 per cent, were located in 195 of the 213 cities having a population in 1900 of at least 20,000. The capital invested in these establishments was $73,925,124, or 58.5 per cent; the salaries, $3,143,805, or 60 per cent; the wages, $18,466,168, or 59.8 per cent; the cost of materials used, $33,563,701, or 54.8 per cent; and the value of products, $70,212,541, or 56 per cent of the corresponding totals for the United States.

There are 16 cities with a population of 20,000 and over in 1900, in each of which carriages and wagons valued at more than $1,000,000 were manufactured as reported at the census of 1905. These in order of rank were: Cincinnati, Ohio; St. Louis, Mo.; South Bend, Ind.; New York, N. Y.; Chicago, Ill.; Racine, Wis.; Columbus, Ohio; Indianapolis, Ind.; Philadelphia, Pa.; Louisville, Ky.; Jackson, Mich.; Rochester, N. Y.; Kalamazoo, Mich.; Toledo, Ohio; Watertown, N. Y.; and Detroit, Mich. Products valued at $42,598,640, or 34 per cent of the total, were manufactured in these 16 cities. There were also a number of smaller cities in which a product in excess of $1,000,000 was reported. These are Flint and Pontiac, Mich.; Moline, Ill.; Connersville, Ind.; Owensboro, Ky.; and Stoughton, Wis.

Materials used.—Table 3 gives separately the cost, and, for some items, the quantity of the principal materials used at the last two censuses, together with percentages of increase.

Perhaps the most striking feature of the table is the decrease in the cost of iron and steel, but the extent of the decrease is more apparent than real, for in 1900 gears were not reported separately, being included with iron and steel. For 1905 there was also a closer segregation from iron and steel, of carriage hardware, lamps, and mountings, which assisted in the large gain in cost for the latter group of 52.6 per cent. The cost of lumber, which ranked with iron and steel as the most important material used in the industry, increased $1,650,187, or 19 per cent. The increase of $558,094, or 27 per cent, in the cost of rubber tires indicates the steadily increasing demand for those parts.

TABLE 3.—*Materials used, by kind, quantity, and cost, with per cent of increase: 1905 and 1900.*

KIND.	CENSUS. 1905	CENSUS. 1900	Per cent of increase.
Total cost	$61,215,228	$53,723,311	13.9
Lumber	$10,338,003	$8,687,816	19.0

Number	3,628,889	3,594,573	1.0
Cost	$5,863,931	$5,205,729	12.6
Axles and springs, purchased	$4,460,759	$4,400,955	1.4
Fuel	$1,175,035	$918,810	27.9
Rent of power and heat	$180,470	$83,493	116.1
All other materials, including mill supplies and freight	$7,330,066	$5,142,713	42.5

[1] Decrease. [2] Not reported separately.

Products.—Table 4 shows separately the kind, quantity, and value of the different products as reported at the censuses of 1900 and 1905, with percentages of increase. The classification is based on the character of the vehicle and its proposed use. The item "all other products" includes the value of parts manufactured other than those that were components of the finished vehicles; the value of all subsidiary products, except that of automobiles, which is given separately; and the amount received for repair work.

TABLE 4.—*Products, by kind, quantity, and value, with per cent of increase: 1905 and 1900.*

KIND.	CENSUS. 1905	CENSUS. 1900	Per cent of increase.
Total value	$125,332,976	$113,234,590	10.7
Family and pleasure carriages:			
Number	937,409	904,639	3.6
Value	$55,750,276	$51,295,393	8.7
Public conveyances:			
Number	2,711	2,218	22.2
Value	$1,314,952	$1,114,090	18.0
Wagons (business, farm, government, municipal, etc.):			
Number	643,755	570,428	12.9
Value	$37,195,230	$31,080,738	19.7
Sleighs and sleds:			
Number	127,455	117,006	8.9
Value	$2,694,560	$2,290,903	17.6
Automobiles:			
Number	199	174	14.4
Value	$235,675	$129,053	82.6
All other products	$28,142,283	$27,324,413	3.0
Carriage bodies, number [1]	8,676	12,735	[2] 31.9
Wagon bodies, number [1]	8,855	8,909	[2] 0.5
Wheels, number [1]	389,266	148,158	162.7

[1] Value included in "all other products." [2] Decrease.

For family and pleasure carriages an increase of 32,770, or 3.6 per cent, is shown in number, and of

$4,454,883, or 8.7 per cent, in value. The value reported for 1905 was 44.5 per cent of the total, a falling off of eight-tenths of 1 per cent. The average value was $57 for 1900 and $59 at the census of 1905. Wagons, which were the second largest class of products at both censuses, increased 73,327, or 12.9 per cent in number and $6,114,492, or 19.7 per cent, in value. The average value rose from $54 for 1900 to $58 for 1905. The automobiles shown are the few that were manufactured as a subsidiary product. The number of carriage bodies reported as manufactured for sale at the census of 1905 decreased 31.9 per cent and the number of wagon bodies five-tenths of 1 per cent. The number of wheels, however, increased 241,108, or 162.7 per cent. Deducting the value of "all other products" from the gross value for each of the two censuses, as shown in Table 4, a value of $97,190,693 results for 1905 and $85,910,177 for 1900. These figures represent the value of the finished vehicles reported at the two censuses and show an increase of $11,280,516, or 13.1 per cent.

Table 5 is a comparative summary of products for 1900 and 1905, by kind, quantity, and value, arranged by states and territories.

TABLE 5.—PRODUCTS, BY KIND, QUANTITY, AND VALUE—COMPARATIVE SUMMARY, BY STATES AND TERRITORIES: 1905 AND 1900.

[1] Included in "all other states" in 1905.
[2] Includes states as follows: Arizona, Indian Territory, Nevada, North Dakota, Wyoming.
[3] Includes states as follows: Indian Territory, Nevada.

In family and pleasure carriages, Ohio ranked first at the census of 1900, having produced 23.6 per cent of the number and 21.9 per cent of the value for the whole country. At the census of 1905, although still ranking first, the state produced only 21.3 per cent of the number and 20.4 per cent of the value. There was an absolute decline in number of 14,264, or 6.7 per cent, but an absolute increase in value of $115,984, or 1 per cent. Indiana reported a marked gain, advancing from third place in 1900 to second at the census of 1905, with an increase of 37,228, or 26.3 per cent, in number and of $2,734,932, or 39.3 per cent, in value.

Michigan ranked next to Indiana, with which it exchanged places during the intercensal period, but, like Ohio, showed a decrease in number, this decrease being 18,365, or 9.5 per cent, although there was a gain of $358,690, or 4.8 per cent, in value. Approximately three-fifths of the number and one-half of the value of family and pleasure carriages made were reported from these states at both censuses.

New York led in the number of public conveyances manufactured, with 27.4 per cent of the entire number reported at the census of 1905 and 29.6 per cent of that reported for 1900. The value for 1905 was $518,469, or 39.4 per cent of the total. Massachusetts was second for 1900, but Connecticut took its place at the census of 1905, with a value of $153,875. Michigan, which reported no public conveyances for 1900, reported 120, with a value of $116,026, at the census of 1905. Ohio and Pennsylvania showed large gains.

At each census the greatest number of wagons was manufactured in Indiana—14.4 per cent of the total at the census of 1905 and 16.5 per cent at the census of 1900. The reduced output reported for 1905 was due to a loss of 38.7 per cent in number of business wagons built, which more than counterbalanced the increase in farm wagons and in government and municipal wagons. The state also held first rank in farm wagons, with 15.5 per cent at the census of 1905 and 16.6 per cent for 1900.

Wisconsin was second at both censuses, the number reported for 1905 being a gain of 13,706, or 19.5 per cent. The value increased $1,088,238, or 32.9 per cent.

Two other states that occupied important positions in the manufacture of wagons were Illinois and Michigan. The total number built in the former state increased 15,669, or 27.8 per cent; in the latter state, 2,370, or 4.8 per cent. The increases in value were $888,617, or 28.3 per cent, in Illinois, and $303,498, or 14.8 per cent, in Michigan.

At the census of 1905 Michigan ranked first in the manufacture of sleighs and sleds, with an output of 41.7 per cent of the total number and 36.3 per cent of the total value. The increase in number was 2,031, or 4 per cent; and in value $131,057, or 15.5 per cent. New York ranked second at the census of 1905 with 15.2 per cent of the number and 22 per cent of the value. The increase was 4,933, or 34 per cent, in quantity and $180,693, or 43.8 per cent, in value.

Exports and imports.—The value of exports of carriages and wagons, and parts thereof, and the value of imports entered for consumption for each year ending June 30, from 1900 to 1905, are shown by the following tabular statement:

Exports and imports of carriages and wagons, and parts thereof: 1900 to 1905.[1]

YEAR ENDING JUNE 30—	Exports (value).	Imports entered for consumption (value).
1905	$3,320,641	$9,660
1904	3,354,801	18,337
1903	3,556,925	26,066
1902	2,490,063	19,640
1901	2,790,178	18,523
1900	2,809,784	29,662

[1] Bureau of Statistics, Department of Commerce and Labor, "Commerce and Navigation of the United States."

There was a loss in exports from 1900 to 1902, followed by a gain for 1903, when the maximum was reached, yet the total value for 1905 was $510,857 more than that for 1900, an increase of 18.2 per cent. The proportion of the total output exported was about the same for 1905 as for 1900, the percentages being 2.7 for the former year and 2.5 for the latter, a very slight gain.

For 1905, 17.8 per cent of the total exports went to the United Kingdom; this was a decrease of $231,888, or 28.2 per cent from 1900. The decrease in the exports to the other European countries, however, was 55.6 per cent. For 1900 the greatest amount exported to the North American continent was to Mexico, but for 1905 the predominant exportation was to the Dominion of Canada, although the trade with Mexico showed a healthy growth. Argentina afforded the best South American market for both 1900 and 1905, 83.1 per cent of the value of exports to South America for 1905 and 76.9 per cent for 1900 going to that country. These exports to Argentina increased from $178,621 for 1900 to $457,587 for 1905, a gain of $278,966, or 156.2 per cent. The East Indies outranked all other countries of Asia for 1900 as well as 1905, but Japan showed the largest value for any single country for 1905. British Australasia was the leading country of Oceania in both years, and British Africa, the principal subdivision of Africa to which carriages and wagons were exported.

The imports are insignificant, and the decrease since 1900 has been $20,002, or 67.4 per cent.

Carriage and wagon materials.—In the report for the census of 1900 the statement was made that in the earliest stages of the carriage and wagon industry almost the entire work of manufacturing was done at the establishment, but that in 1900 there were very few, if any, manufacturers who produced all the parts. The manufacture of carriage and wagon materials as a separate industry has been steadily growing. Table 6 is a comparative summary of the general statistics for this industry at the censuses of 1890, 1900, and 1905.

TABLE 6.—*Carriage and wagon materials—comparative summary: 1890 to 1905.*

	1905	1900	1890
Number of establishments	632	588	539
Capital	$26,024,053	$19,085,775	$13,028,161
Wage-earners, average number	17,160	15,387	9,996
Total wages	$7,484,450	$5,987,267	$4,366,233
Miscellaneous expenses	$1,930,469	$1,202,666	$321,743
Cost of materials used	$16,312,663	$13,048,608	$7,387,904
Value of products	$30,535,873	$25,027,173	$16,262,293

Every item of the table shows a substantial increase at each census. The increase in total wages was $1,621,034, or 37 per cent, from 1890 to 1900 and $1,497,183, or 25 per cent, from 1900 to 1905. The increase in value of products was $8,764,880, or 53.9 per cent, from 1890 to 1900 and $5,508,700, or 22 per cent, from 1900 to 1905.

A comparison of gains in carriage and wagon materials from census to census with those shown in Table 1 for carriages and wagons shows that the value of products increased more rapidly in the former than in the latter industry. In 1890 the combined products were valued at $118,942,634, of which the value of carriage and wagon materials constituted 13.7 per cent; for 1900 the combined products were valued at $138,261,763, and carriage and wagon materials formed 18.1 per cent thereof, and for 1905 the combined products were valued at $155,868,849, to which carriage and wagon materials contributed 19.6 per cent. The entire product of the carriage and wagon material factories, however, is not disposed of to carriage and wagon manufacturers; blacksmiths and wheelwrights use a part of the products in their custom and repair work.

The detailed statistics for the carriage and wagon industry as reported at the census of 1905 are shown, by states and territories, in Table 7.

TABLE 7.—CARRIAGES AND WAGONS—DETAILED

		United States.	Alabama.	Arkansas.	California.	Colorado.
1	Number of establishments	4,956	23	16	184	35
2	Capital, total	$126,320,604	$558,163	$314,919	$1,676,158	$262,888
3	Land	$10,867,701	$30,025	$37,800	$354,140	$60,800
4	Buildings	$23,186,108	$75,103	$43,804	$232,150	$57,600
5	Machinery, tools, and implements	$11,785,633	$80,952	$42,914	$268,598	$35,965
6	Cash and sundries	$80,481,162	$372,083	$190,401	$821,270	$108,523
7	Proprietors and firm members	6,022	27	15	236	39
	Salaried officials, clerks, etc.:					
8	Total number	5,058	28	12	47	9
9	Total salaries	$5,239,043	$28,021	$8,373	$48,675	$8,900
	Officers of corporations—					
10	Number	866	6	1	12	2
11	Salaries	$1,598,251	$10,780	$900	$20,794	$2,500
	General superintendents, managers, clerks, etc.—					
12	Total number	4,192	22	11	35	7
13	Total salaries	$3,640,792	$17,241	$7,473	$27,881	$6,400
	Men—					
14	Number	3,443	21	9	28	6
15	Salaries	$3,306,893	$16,641	$6,745	$25,148	$6,300
	Women—					
16	Number	749	1	2	7	1
17	Salaries	$333,899	$600	$728	$2,733	$100
	Wage-earners, including pieceworkers, and total wages:					
18	Greatest number employed at any one time during the year	74,698	459	170	1,168	200
19	Least number employed at any one time during the year	48,436	207	115	810	157
20	Average number	60,722	370	134	938	177
21	Total wages	$30,878,229	$161,399	$60,898	$684,812	$129,557
	Men 16 years and over—					
22	Average number	59,411	350	132	932	171
23	Wages	$30,525,515	$157,828	$60,598	$683,157	$128,309
	Women 16 years and over—					
24	Average number	870			1	
25	Wages	$266,674			$100	
	Children under 16 years—					
26	Average number	441	20	2	5	6
27	Wages	$86,040	$3,571	$300	$1,555	$1,248
	Average number of wage-earners, including pieceworkers, employed during each month:

SHIPBUILDING

SHIPBUILDING.

The statistics for shipbuilding at the census of 1905 cover the calendar year 1904. Frequently comparisons are made with the Twelfth and prior censuses in the form of "1905," "1900," etc.

In the general tables of this report the value of products is confined to the value of the work done during the census year. In order to show the numerical output and value of ships launched during the census year, detailed tables are added which give the number of each class of vessels launched during the year with their tonnage and contract value.

In cases where engine construction and shipbuilding work were combined in the same plant, and shipbuilding operations were secondary to the foundry and machine shop or other products reported, the statistics relating to capital invested, labor, cost of materials, etc., were not included in the general tables for the shipbuilding industry, although the vessels launched by such establishments appear in connection with certain detailed tables of this report. On the other hand, whenever the value of the shipbuilding operations predominated, statistics for such establishments appear in the following tables, products other than shipbuilding being classified as "all other products." Statistics of the production of marine engines, marine boilers, anchors, chains, masts, and other shipbuilding supplies by establishments not engaged in shipbuilding are not included in this report.

THE COMBINED INDUSTRY.

Table 1 is a comparative summary, giving the general statistics of the combined industry—iron and steel shipbuilding, and wooden shipbuilding—exclusive of governmental establishments, from 1850 to 1905, with the per cent of increase for each census period.

TABLE 1.—COMPARATIVE SUMMARY, WITH PER CENT OF INCREASE: 1850 TO 1905.

	CENSUS.							PER CENT OF INCREASE.

[1] Exclusive of the statistics of 20 establishments engaged primarily in the manufacture of other products. These establishments reported shipbuilding products to the value of $657,342.
[2] Decrease.
[3] Includes proprietors and firm members with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported separately.
[5] Not reported.

For the shipbuilding industry the period covered by the table is particularly interesting, marking as it does the half century of progress during which the transition from wood to iron and steel in the construction of ships radically altered conditions in the industry. In a limited manner the table reflects these changes. While the number of establishments engaged in the construction of ships did not increase materially during the fifty-five years, the capital invested in the industry increased twenty-one fold and the value of the product nearly fourfold. These changes indicate that, as the construction of iron and steel ships has grown in importance, capital has become far more essential to the development of the industry than was the case when ships were constructed of wood only.

Since 1900 the number of shipbuilding plants has apparently decreased, notwithstanding that in the other statistical items of importance there were substantial gains. In a measure this is explained by the fact that at the census of 1900 a number of small boat builders and repairers were included that did not prove of sufficient importance to be included in the factory census of 1905. The operations of the establishments omitted on this account, however, were inconsiderable and consequently their omission does not affect materially the other statistical items shown in the table. At the census of 1880 there were practically twice as many establishments engaged in the industry as at the census of 1905. This fact, taken in conjunction with the increase in capital and products, shows the progressive concentration of shipbuilding in large establishments made necessary by the altered conditions in the industry, to which reference has already been made.

The capital invested in the industry increased during the years between 1900 and 1905 at a far greater rate than the value of the products. This condition was more marked than that which characterized the industry during the previous intercensal period, and it is explained by the extremely unsatisfactory state of the shipbuilding industry during 1904, which was especially marked in the shipbuilding operations on the Great Lakes. Owing to this depression it is probable that the increase in the capital invested is a truer index to the progress of the industry since 1900 than the value of the products.

Branches of the industry.—In Table 2 are shown separately the operations of private establishments engaged primarily in the construction of iron and steel vessels, and those building principally wooden ships and boats, at the censuses of 1900 and 1905.

TABLE 2.—COMPARATIVE SUMMARY, BY BRANCHES: 1905 AND 1900.

	1905					1900					PER CENT OF INCREASE.	
	Total.	Iron and steel.	Per cent of total.	Wooden.	Per cent of total.	Total.	Iron and steel.	Per cent of total.	Wooden.	Per cent of total.	Iron and steel.	Wooden.

[1] Decrease.

The notable feature of the table is the increase in the capital invested in iron and steel shipbuilding. This increase amounted to $41,688,696, which was more than twice the amount invested in wooden shipbuilding at the census of 1905. It is not surprising, therefore, that at the later census the capital invested in the iron and steel branch of the industry constituted 83.5 per cent of the total capital invested in shipbuilding.

The division of the number of establishments engaged in shipbuilding between the two branches of the industry is more disproportionate than the division of capital, the establishments engaged in wooden construction work constituting 95.1 per cent of the total number. This fact, taken in conjunction with the division of the capital, indicates clearly the dissimilar character of the operations of each. The great majority of the establishments engaged in the construction of iron and steel vessels are of great size, requiring the most costly and extensive equipment; whereas a large proportion of the establishments engaged in wooden construction work are small yards which perform minor repairs on small vessels and turn out wooden vessels of comparatively small tonnage.

It is evident that the depression which characterized the industry in 1904 fell more heavily upon the establishments engaged in iron and steel construction work than upon those engaged in wooden construction work. The following tabular statement, which presents the average capital and average value of the product per establishment for both branches of the industry at the last two censuses, illustrates this fact more clearly than Table 2:

	AVERAGE PER ESTABLISHMENT.			
	1905		1900	
	Capital.	Value of products.	Capital.	Value of products.
Iron and steel	$1,880,153	$1,062,098	$1,359,990	$1,144,721
Wooden	19,267	23,333	16,464	22,732

The statement shows that the productivity of the capital invested in the average establishment engaged

in wooden shipbuilding at the census of 1900, when conditions were fairly normal, continued practically unaffected by the depression at the census of 1905; whereas in the case of the average establishment in the iron and steel branch of the industry the decline in the productivity of the capital plainly reflects the unnatural conditions at the later census, indicating that a large proportion of the capital was idle.

Materials used.—Table 3 shows the cost of materials used at the censuses of 1890, 1900, and 1905, distributed according to kind.

The growth in importance of iron and steel as materials in shipbuilding is well illustrated by the table. At the census of 1890 the cost of iron and steel constituted a less important item in the expenditure for materials than the cost of lumber, but at the census of 1905, the cost of the former item constituted 41.2 per cent and the cost of the latter only 17.9 per cent of the amount paid out for materials.

The decrease in wooden shipbuilding is further indicated by the decrease since 1900 in the amount of money expended for cordage, masts and spars, blocks, oakum and pitch—materials which belong particularly to that branch.

TABLE 3.—*Materials used, by kind and cost, with per cent of total: 1890 to 1905.*

KIND.	1905		1900		1890	
	Amount.	Per cent of total.	Amount.	Per cent of total.	Amount.	Per cent of total.
Total	$37,463,179	100.0	$33,474,896	100.0	[1] $16,925,109	100.0

Wooden construction	9,724,231	11.8	10,295,530	13.8	12,933,149	34.0	14,129,421	38.4
Small boats under 5 tons	3,001,292	3.6	1,968,835	2.6	1,392,084	3.7	876,999	2.4
Repair work	22,829,040	27.6	23,134,436	31.0	10,012,389	26.3	16,607,614	45.4
All other products	3,818,972	4.6	13,678,533	18.4	2,176,942	5.7	(1)	.....

[1] Not reported separately.

Table 4 shows the rapid growth in iron and steel construction during the past twenty-five years. In marked contrast is the decrease in wooden construction during the period. At the census of 1880 the value of the work done upon wooden vessels of 5 tons and over was nearly three times as great as the value of work done upon iron and steel vessels of the same class, but a quarter of a century later conditions were reversed and the value of work done on vessels constructed of iron and steel was over four times that of work done on vessels built of wood.

The increase since 1900 of $1,032,457, or 52.4 per cent, in the production of boats under 5 tons is a notable feature of the table. This increase is due to the demand for small boats, both for business and pleasure, driven by internal combustion engines, and has resulted naturally from marked improvements in engines of this type which have made them most adaptable and efficient sources of power for the propulsion of small boats.

The noticeable falling off in the value of "all other products" is due largely to the increasing tendency among shipbuilders to eliminate minor products and to confine themselves to the principal products of the industry. Many of the minor materials necessary in ship construction are now manufactured in large quantities by establishments specializing in their production, and it is cheaper for the shipbuilder to buy them in the open market than to produce them himself.

Table 5 presents the states which led in the shipbuilding industry at the census of 1905, ranked according to capital and value of products reported at each census during the past twenty-five years.

TABLE 5.—*Rank, according to capital and value of products, of states having products valued at one million dollars and over for 1905: 1880 to 1905.*

STATE.	RANK ACCORDING TO—							
	Capital.				Value of products.			
	1905	1900	1890	1880	1905	1900	1890	1880
California	9	4	6	3	5	3	5	7
Connecticut	15	16	12	12	7	16	11	13
Delaware	11	11	7	7	13	11	9	5
Maine	14	9	10	8	9	8	6	3
Maryland	7	6	8	5	8	7	10	8
Massachusetts	6	12	9	4	6	10	8	4
Michigan	8	7	2	9	11	6	2	6
New Jersey	5	8	5	6	4	5	7	10
New York	4	3	1	2	1	2	1	1
Ohio	2	5	3	11	10	9	3	9
Pennsylvania	3	2	4	1	2	1	4	2
Virginia	1	1	18	17	3	4	18	22
Washington	10	14	21	23	12	13	21	21

Of the leading states shown in the table, New York and Pennsylvania appear to have undergone the least marked variations in rank, and in both capital and value of product each has held the first rank or has been very close to the leader throughout the quarter of a century. The leadership of these two states has been most marked in the value of the product, New York having been first at three of the four censuses and second in 1900, when Pennsylvania led. The most marked progress appears to have been made by Virginia, which during the twenty-five years rose from twenty-second to third rank in value of products and from seventeenth to first rank in capital invested.

The Pacific Coast district is represented by California and Washington, of which the former has held an important position in the industry throughout the period shown, while the latter is evidently making rapid progress. Of the states on the Great Lakes, Ohio and Michigan are the leaders, the former being second in capital and tenth in value of the product at the census of 1905.

The industry by watershed districts.—Table 6 shows the distribution of the totals for the United States, by watershed districts, at the census of 1905.

TABLE 6.—SUMMARY, BY WATERSHED DISTRICTS, WITH PER CENT OF TOTAL: 1905.

All other products	$3,818,972	$2,750,738	72.0	$380,868	10.0	$230,720	6.0	$456,646	12.0

At the census of 1905 nearly three-fourths of the aggregate value of the products of the shipbuilding industry was produced by the establishments located in the Atlantic and Gulf district. The number of establishments engaged in the industry in the Great Lakes district was nearly double the number of shipbuilding plants in the Pacific Coast district, but the value of the output of the latter was slightly greater than that of the former district. In the Great Lakes district a much greater number of small vessels of less than 5 tons are built than is the case in the Pacific Coast district, and it is natural, therefore, that there should be a larger number of small establishments the products of which are in no way comparable from the standpoint of value to those of the great shipyards on the western coast, which in two cases at least build war ships of the largest size.

It would appear from the table that for the products aggregating approximately the same value, over four times as much capital is required in the Great Lakes district as in the Pacific Coast district. This is explained in part by the fact that the returns of capital for the establishments in the Great Lakes district included numerous dry docks aggregating a far greater value than was reported for this item of fixed capital by establishments in the Pacific Coast district, and in part by the inclusion of a class of assets by one of the largest establishments on the Lakes, amounting to several millions of dollars, which did not appear in the capital of any of the large shipbuilding plants on the Pacific Coast. Finally, it is probable that owing to the depression which characterized the industry during the census year, a larger percentage of the capital employed in shipbuilding on the Great Lakes was unproductive than was the case on the Pacific Coast, where the construction of Government war ships formed at that time the greater proportion of the work performed by the largest shipbuilders on the coast. One large company on the Lakes was practically without construction work during August, 1904, and the entire year in this district up to the closing months was one of unusual depression in the industry.

The unsatisfactory conditions prevailing in the shipbuilding industry on the Great Lakes during the census year is further disclosed in Table 7, which compares the returns made by establishments in the two branches of the industry on the Great Lakes at the censuses of 1900 and 1905.

TABLE 7.—COMPARATIVE SUMMARY FOR THE GREAT LAKES DISTRICT, BY BRANCHES, WITH PER CENT OF INCREASE: 1905 AND 1900.

	IRON AND STEEL.			WOODEN.		
	1905	1900	Per cent of increase.	1905	1900	Per cent of increase.
Number of establishments	11	8	37.5	167	114	46.5
Capital	$28,556,593	$12,509,788	128.3	$3,233,810	$2,675,385	20.9
Salaried officials, clerks, etc., number	286	140	104.3	118	77	53.2
Salaries	$307,030	$230,330	33.3	$108,120	$76,657	41.0
Wage-earners, average number	3,910	6,388	[1]38.8	1,833	2,129	[1]13.9
Total wages	$2,279,704	$3,130,005	[1]27.2	$941,586	$1,201,060	[1]21.6
Miscellaneous expenses	$617,574	$405,446	52.3	$228,143	$151,020	51.1
Cost of materials used	$2,653,053	$4,003,854	[1]33.7	$929,287	$962,396	[1]3.4

Vessels of 5 tons and over	$4,382,456	$5,183,628	[1]15.5	$487,648	$679,804	[1]28.3
Small boats under 5 tons	$80,000	.....	.....	$752,753	$333,034	126.0
Repair work	$2,196,987	$2,028,639	8.3	$1,096,228	$1,617,307	[1]32.2
All other products	$155,818	$2,035,038	[1]92.3	$225,050	$76,404	194.6

[1] Decrease.

Both the number of establishments and the capital invested in them increased during the intercensal period, but with respect to all the remaining items of importance shown in the table marked decreases appear for both iron and steel and wooden shipbuilding. The decreases were particularly marked in the iron and steel branch of the industry, the value of the product falling off over one-fourth of the value of the output for 1900. Some idea of the depression in the industry which marked the census year 1904 may be obtained from the report of the Commissioner of Navigation for the fiscal year ending June 30, 1904, from which it appears that on July 1, 1904, practically no construction work was in progress in the lake region. When this condition is contrasted with 26 steel ships with an aggregate tonnage of 103,667 tons reported to the Commissioner of Navigation as under construction in shipbuilding plants on the Great Lakes, July 1, 1905, conditions in the industry during 1904 are brought plainly into view. The losses disclosed by Table 7, then, were due to a temporary derangement of the industry which unfortunately occurred in the census year. As a matter of fact the increases in the number of establishments and capital invested in the industry may properly be taken to indicate that shipbuilding on the Great Lakes is increasing instead of decreasing.

GOVERNMENTAL ESTABLISHMENTS.

Government navy yards engaged in shipbuilding and repair work during the census year, listed in the order of the magnitude of their operations, were as follows:

Brooklyn navy yard.....New York, N. Y.
Boston navy yard.....Boston, Mass. (Charlestown).
Navy yard and station.....Norfolk, Va.
Mare Island navy yard.....Vallejo, Cal.
Puget Sound navy yard.....Bremerton, Wash.
League Island navy yard.....Philadelphia, Pa.
Portsmouth navy yard.....Portsmouth, N. H. (Kittery, Me.).
Navy yard.....Pensacola, Fla.
Naval station.....Port Royal, S. C.

Table 8 is a comparative summary of the operations of these 9 navy yards for 1905 and the operations of the 8 yards reported as engaged in the industry at the census for 1900.

TABLE 8.—*Governmental establishments—comparative summary, with per cent of increase: 1905 and 1900.*

	1905	1900	Per cent of increase.
Number of establishments	9	8	12.5
Capital	$56,921,404	$54,280,511	4.9
Salaried officials, clerks, etc., number	567	539	5.2
Salaries	$699,062	$464,997	50.3
Wage-earners, average number	12,204	7,684	58.8
Total wages	$9,722,764	$6,217,955	56.4
Miscellaneous expenses	$111,712	$29,064	284.4
Cost of materials used	$6,731,931	$3,802,345	77.0
Value of products, including repair work	$17,265,469	$11,022,312	56.6

An increasing navy has compelled the Government to equip the navy yards adequately for the repair work necessarily resulting from the larger number of new vessels now continually in commission. In addition Government yards are also undertaking the construction of the largest types of war ships, one of which was completed during 1904, and the increase in value of products revealed by the table reflects these conditions.

VESSELS LAUNCHED, SMALL BOATS, AND REPAIR WORK.

In the preceding sections of this report the statistics presented for the shipbuilding industry include only the value of work done during the census year. In the following tables statistics are presented concerning vessels launched during the year, irrespective of the time taken in their construction.

In explanation of a number of the tables which follow, wherein tonnage is shown, it should be said that gross and net tonnage is the gross and net load capacity of a vessel in tons. By methods prescribed by law, now practically uniform for the leading maritime countries, the hull of a vessel is carefully measured and the total capacity in cubic feet is ascertained. This quantity is

then divided by 100, which gives the gross tonnage of the vessel. In order to obtain the net tonnage the space occupied by the quarters of the crew and officers, by the machinery—boilers, engines, etc.—by the gear used in navigation, and by the double bottom, when not available for cargo, stores, or fuel, is deducted from the total capacity of the hull in cubic feet and the result divided by 100. Differing from these two measures is the displacement tonnage of a vessel. Displacement tonnage is merely the weight of the volume of water displaced, which is equal to the weight of the floating vessel and its load. It is necessary, therefore, in referring to the displacement of a vessel to specify under what conditions, whether with or without load, the displacement is calculated. The tonnage of war vessels of the United States Navy is always given in displacement tonnage, which is the weight of the vessel in ordinary cruising condition. While gross tonnage and displacement tonnage are thus not by any means the same, it is necessary to combine the two in order to obtain a total which will approximately represent the total tonnage launched during the year. This method has been followed in this report wherever Government vessels are shown with merchant vessels.

In the tables which follow tonnage shown for 1905 is gross unless otherwise specified. It is impossible to indicate for previous censuses the quantity of displacement tonnage included in the figures, but owing to the fact that the building of Government war ships has only recently become prominent in the industry, it is probable that for censuses prior to the census of 1900 displacement tonnage formed a comparatively small proportion of the totals shown in the tables.

Vessels of 5 tons and over.—In Table 9 is presented the number of iron and steel vessels and the number of wooden vessels launched by private yards, together with their tonnage and value, as reported at each census from 1880 to 1905.

TABLE 9.—NUMBER, TONNAGE, AND VALUE OF VESSELS OF FIVE TONS AND OVER LAUNCHED BY PRIVATE SHIPYARDS, WITH PER CENT OF INCREASE: 1880 TO 1905.

CLASS.	CENSUS.				PER CENT OF INCREASE.		
	1905	1900	1890	1880	1900 to 1905	1890 to 1900	1880 to 1890
All classes:							
Number of vessels	[1] 2,248	2,081	1,353	2,415	8.0	53.8	[2] 44.0
Tonnage	[3] 700,852	687,159	484,640	498,878	2.0	41.8	[2] 2.9
Value	$73,471,026	$35,750,473	$24,483,995	$19,225,714	105.5	46.0	27.4
Iron and steel:							
Number	155	134	88	67	15.7	52.3	31.3
Tonnage	[4] 328,819	262,516	123,973	31,347	25.3	111.8	295.5
Value	$63,682,960	$25,454,943	$11,550,846	$5,096,293	150.2	120.4	126.7
Wooden:							
Number	2,093	1,947	1,265	2,348	7.5	53.9	[2] 46.1
Tonnage	[5] 372,033	424,643	360,667	467,531	[2] 12.4	17.7	[2] 22.9
Value	$9,788,066	$10,295,530	$12,933,149	$14,129,421	[2] 4.9	[2] 20.4	[2] 8.5

[1] Includes 134 vessels of 22,327 gross tonnage, valued at $463,018, which were launched by establishments engaged primarily in the manufacture of other products.
[2] Decrease.
[3] Includes 174,505 tons displacement—Government vessels.
[4] Includes 169,803 tons displacement—Government vessels.
[5] Includes 4,702 tons displacement—Government vessels.

Comparison of tonnage and value of vessels launched, as reported for 1905, can not be made with the statistics for prior censuses without important reservations. As previously stated, the value ($53,119,935) reported for 1905 for vessels of 5 tons and over, in the general tables, represents only the value of the work done during the census year, while the value ($73,471,026) in Tables 9 and 14 represents the total value or contract price of the vessels launched during that time. The difference ($20,351,091) is occasioned largely by the great amount of construction work on war vessels for the Government, which required more than one year to complete. At prior censuses the value of the year's work was not reported separately, and although Government construction was not so prominent a feature, it is impossible to say to what extent the totals at those censuses are not strictly comparable with those for the census of 1905.

Although the number of ships launched as reported at the census of 1905 was less by 167 than the number launched twenty-five years before, yet the tonnage increased 40.5 per cent during the period, and the average tonnage of the vessels launched, 50.9 per cent. In this connection it is interesting to note that the average value of the vessels launched in 1880 was only $7,961, whereas in 1905 the average was $32,683.

Since 1900 the increases in tonnage and in number have been slight but the value of the ships launched more than doubled. Tables 10 and 11 throw some light on the unusual increase in this item.

TABLE 10.—*Number, tonnage, and value of vessels of five tons and over launched during 1904 by all establishments, classified according to service.*

CLASS.	Aggregate.	Merchant service.	GOVERNMENT SERVICE.		
			Total.	By private shipyards.	By Government shipyards.
All classes:					
Number	[1] 2,279	2,195	84	53	31
Tonnage	728,104	526,347	[2] 201,757	174,505	27,252
Value	$79,918,035	$31,172,592	$48,745,443	$42,298,434	$6,447,009
Iron and steel:					
Number	172	121	51	34	17
Tonnage	352,669	159,016	[2] 193,653	169,803	23,850
Value	$69,944,092	$21,978,001	$47,966,091	$41,704,959	$6,261,132
Wooden:					
Number	2,107	2,074	33	19	14
Tonnage	375,435	367,331	[2] 8,104	4,702	3,402
Value	$9,973,943	$9,194,591	$779,352	$593,475	$185,877

[1] Includes 134 vessels of 22,327 gross tonnage, valued at $463,018, which were launched by establishments engaged primarily in the manufacture of other products.
[2] Displacement tonnage.

Table 10 shows that although only 3.7 per cent of the total number of vessels launched during 1904 were destined for Government service, yet these vessels represented 27.7 per cent of the tonnage and 61 per cent of the aggregate value of all vessels launched.

Of the 53 ships launched for the Government by private yards, 13 were war ships of 1,000 tons and over, as shown in Table 11, aggregating 154,170 tons displacement and a contract value of $39,513,600. Referring to Table 10, it will be seen that the value of these war ships constituted over one-half of the value of vessels of 5 tons and over of all descriptions launched by private establishments during 1904, and that this value was greater by $3,763,127 than the value of vessels of 5 tons and over of all descriptions launched by private yards at the census of 1900. It is evident, therefore, that the great increase in value since 1900 has resulted largely from the unusual activity in construction work for the Navy.

TABLE 11.—STEEL VESSELS OF 1,000 TONS AND OVER FOR THE UNITED STATES NAVY LAUNCHED DURING 1904 BY PRIVATE SHIPYARDS.[1]

NAME OF VESSEL.	Type.	Builder.	Place of construction.	Normal displacement (tons).	Contract price.
Total				154,170	$39,513,600
Georgia	First-class battle ship	Bath Iron Works	Bath, Me	14,948	3,590,000
Louisiana	First-class battle ship	Newport News Shipbuilding Co	Newport News, Va	16,000	3,990,000
Nebraska	First-class battle ship	Moran Bros	Seattle, Wash	14,948	3,733,600
New Jersey	First-class battle ship	Fore River Shipbuilding Co	Quincy, Mass	14,948	3,405,000
Rhode Island	First-class battle ship	Fore River Shipbuilding Co	Quincy, Mass	14,948	3,405,000

Dubuque	Gunboat	Gas Engine and Power Co. and Chas. L. Seabury Co. Cons.	Morris Heights, N. Y	1,085	295,000
Paducah	Gunboat	Gas Engine and Power Co. and Chas. L. Seabury Co. Cons.	Morris Heights, N. Y	1,085	355,000

[1] Annual Report of the Chief of the Bureau of Construction and Repair, United States Navy Department, 1905.

To supplement the information in Table 11, the displacement tonnage of vessels of 1,000 tons and over launched during 1904 from Government yards is shown in Table 12.

TABLE 12.—*Steel vessels of 1,000 tons and over launched during 1904 by Government shipyards.*[1]

NAME.	Type.	Place of construction.	Normal displacement (tons).	Value.
Total			19,600	$4,952,000
Connecticut	First-class battle ship	Brooklyn navy yard	16,000	4,212,000
Cumberland	Steel training bark	Boston	1,800	370,000
Intrepid	Steel training bark	Mare Island navy yard	1,800	370,000

[1] Annual Report of the Chief of the Bureau of Construction and Repair, United States Navy Department, 1905.

If the displacement tonnage of the war ships in Table 11 be added to the displacement of the battle ship *Connecticut* shown in Table 12, the aggregate, 170,170 tons (displacement), will represent the tonnage output of war ships of 1,000 tons and over for the year.

Table 13 shows the net tonnage of the vessels launched for the merchant marine of the United States, at the census of 1905.

TABLE 13.—*Net tonnage of merchant vessels of five tons and over launched during 1904 by private shipyards, classified according to kind of trade, by geographic divisions.*

DIVISION.	Total net tonnage.	NET TONNAGE OF VESSELS BUILT FOR—			
		Foreign trade.	Coastwise trade.	Lake and river trade.	Canal trade.
United States	450,614	23,504	115,699	306,003	5,408
North Atlantic	292,121	22,140	90,887	174,018	5,076
South Atlantic	45,453	840	9,274	35,105	234
North Central	70,130	19	.....	70,111	.....
South Central	20,250	195	2,000	17,957	98
Western	22,660	310	13,538	8,812	.....

The table plainly indicates the importance of lake and river traffic to the shipbuilding of this country. Of the total net tonnage launched for the merchant marine of the United States during the census year, 67.9 per cent was destined for this trade. Vessels for

coastwise and lake and river service are required by law to be American built. This fact has made it possible for shipbuilding to maintain a firm footing in this country.

Of the total net tonnage of merchant vessels launched during the census year 64.8 per cent was built in shipyards of the North Atlantic division, which comprises the New England states, and New York, New Jersey, and Pennsylvania. Of the total net tonnage launched by shipyards in this division, 59.6 per cent was intended for the lake and river trade.

The comparative unimportance of shipbuilding for foreign trade in the United States is indicated by the fact that of the total net tonnage launched for merchant service, only 5.2 per cent was destined for this trade, nearly the whole of which was built in the shipyards of the North Atlantic division.

In Table 14 is presented the number, tonnage, and value of vessels of 5 tons and over launched by private shipyards classified according to motive power, as reported at each census from 1880 to 1905, with percentages of increase.

TABLE 14.—NUMBER, TONNAGE, AND VALUE OF VESSELS OF FIVE TONS AND OVER LAUNCHED BY PRIVATE SHIPYARDS, CLASSIFIED ACCORDING TO MOTIVE POWER, WITH PER CENT OF INCREASE: 1880 TO 1905.

CLASS.	CENSUS.				PER CENT OF INCREASE.		
	1905	1900	1890	1880	1900 to 1905	1890 to 1900	1880 to 1890

Value	$99,300	$225,374	$503,800	$1,739,975	[2] 55.9	[2] 55.3	[2] 71.0

[1] Includes 134 vessels of 22,327 gross tonnage, valued at $463,018, which were launched by establishments engaged primarily in the manufacture of other products.
[2] Decrease.
[3] Includes 174,505 tons displacement—Government vessels.
[4] Not reported separately.

The decrease since 1890 in tonnage and value of sail vessels is a marked feature of the table. The decreases in these items, taken in conjunction with a slight increase during the fifteen years in the number of vessels launched, indicate a falling off in the average size and value of vessels of this class.

In Table 15 the activity in shipbuilding of the watershed districts of the United States at the census of 1905 is indicated by the number, tonnage, and value of vessels launched from the private shipyards in each district, classified according to motive power.

In every class of vessels shown in the table the shipyards in the Atlantic and Gulf district launched vessels aggregating a greater tonnage and value than the combined totals for the shipyards in the other districts. Although the Great Lakes district outranked the Pacific Coast in tonnage the value of the vessels launched from the shipyards in the latter district was over three times as great as the value of the vessels launched in the former. This difference was due to the fact that 65.8 per cent of the tonnage launched in the Pacific Coast district was displacement tonnage of war vessels, the value of which per ton was much greater than the average tonnage value of the vessels launched in the Great Lakes district, which were practically all freight and passenger steamers for lake traffic. In fact, the tonnage of ships built for the merchant marine by shipyards on the Great Lakes was nearly three times as great as that built for merchant service on the Pacific Coast. In the same way the ascendancy of the Atlantic and Gulf district over the Great Lakes in the tonnage of steam vessels launched is due largely to the inclusion of the displacement tonnage of war ships built on the Atlantic Coast. If the displacement tonnage were eliminated from the figures for the Atlantic and Gulf district, the remaining gross tonnage would be only 17,477 tons in excess of the gross tonnage of the steam vessels launched in the Great Lakes district. As has already been pointed out in this report, shipbuilding on the Great Lakes was at a very low ebb during the census year, and thus the table does not show a normal year's output. There is no doubt, therefore, that under normal conditions the tonnage output of steam vessels for the merchant marine is much greater in the Great Lakes district than for any of the other watershed districts.

TABLE 15.—*Number, tonnage, and value of vessels of five tons and over launched during 1904 by private shipyards, classified according to motive power, by watershed districts.*[1]

CLASS.	Atlantic and Gulf.	Great Lakes.	Mississippi Valley.	Pacific Coast.
All classes:				
Number	1,238	160	612	238
Tonnage	[2] 449,641	[3] 81,379	90,194	[4] 79,638
Value	$52,256,195	$4,557,067	$875,843	$15,781,921
Steam vessels:				
Number	208	31	26	49
Tonnage	[2] 206,813	[3] 68,684	9,390	[4] 65,180
Value	$45,789,186	$4,112,639	$403,800	$15,244,745
Barges and canal boats:				
Number	591	28	570	85
Tonnage	185,646	6,085	80,628	10,564
Value	$3,048,104	$136,953	$460,149	$176,163
Sail vessels:				
Number	292	36	[5]	21
Tonnage	55,523	5,712	[5]	3,380
Value	$3,150,497	$225,245	[5]	$244,377
Power vessels, other than steam:				
Number	147	65	16	83
Tonnage	1,659	898	176	514
Value	$268,408	$82,230	$11,894	$116,636

[1] Includes 134 vessels of 22,327 gross tonnage, valued at $463,018, which were launched by establishments engaged primarily in the manufacture of other products.
[2] Includes 121,367 tons displacement—Government vessels.
[3] Includes 715 tons displacement—Government vessels.
[4] Includes 52,423 tons displacement—Government vessels.
[5] Two sail vessels included in figures for Pacific Coast district, to avoid disclosing individual operations.

Table 16 shows the output of the Great Lakes in steel and wooden vessels at the censuses of 1900 and 1905.

TABLE 16.—*Number, tonnage, and value of steel and wooden vessels of five tons and over launched by private shipyards on the Great Lakes, with per cent of increase: 1905 and 1900.*

CLASS.	1905	1900	Per cent of increase.
All classes:			
Number	160	128	25.0
Gross tonnage	[1] 81,379	111,241	[2] 26.8
Net tonnage	62,869	86,942	[2] 27.7
Value	$4,557,067	$5,863,432	[2] 22.3
Steel vessels:			
Number	24	24	.....
Gross tonnage	69,400	96,328	[2] 28.0
Net tonnage	51,479	74,229	[2] 30.6
Value	$4,100,782	$5,183,628	[2] 20.9
Wooden vessels:			
Number	136	104	30.8
Gross tonnage	11,979	14,913	[2] 19.7
Net tonnage	11,390	12,713	[2] 10.4
Value	$456,285	$679,804	[2] 32.9

[1] Includes 715 tons displacement—Government vessels. [2] Decrease.

In view of what has already been said it will be understood that the losses which the table appears to indicate were due to a temporary depression in the industry and not to an actual decrease during the intercensal period.

In Table 17 the states from whose shores vessels valued at a million dollars or over were launched at the census of 1905, are ranked according to the value of vessels launched, for the censuses of 1900 and 1905.

At the census of 1900 the first four places were held by states on the Atlantic coast—Pennsylvania, Maine, Virginia, and New York, in the order named—the fifth by Michigan, on the Great Lakes, and the sixth by California, on the Pacific Coast. Five years later the rank of each of the 6 leading states underwent a change, with the exceptions of Pennsylvania and Virginia, which held first and third places, respectively, at both censuses; California rising to second place; Massachusetts supplanting New York in fourth place; Maine dropping to fifth place; and the state of Washington rising from eleventh to sixth place.

In the majority of cases the rank for steel vessels coincides or closely approximates the rank for all classes, indicating that the production of this class of vessels controls in general the rank of the state in shipbuilding. An exception in this respect exists in the case of Maine. At both censuses this state held the primacy in the building of wooden vessels, and at the census of 1900 the high rank of the state in the shipbuilding industry was due evidently to this fact.

In the launching of steel vessels Washington shows a truly remarkable rise in importance. From a position of insignificance in 1900 the state reached fifth place in this important branch of the industry at the census of 1905. The rise of Massachusetts in the production of steel vessels during the intercensal period was also notable.

TABLE 17.—*Rank of principal states according to value of vessels of five tons and over launched by private shipyards: 1905 and 1900.*

STATE.	ALL CLASSES.		STEEL VESSELS.		WOODEN VESSELS.	
	1905	1900	1905	1900	1905	1900
California	2	6	3	7	5	3
Connecticut	8	15	8	.....	3	5
Delaware	13	7	13	4	8	12
Maine	5	2	7	11	1	1

Virginia	3	3	15	14	7	.....
Washington	6	5	11	6	14	.....

Steam and other power vessels.—The construction of steam vessels now constitutes a large proportion of the shipbuilding operations of the United States. At the censuses prior to 1905 power vessels other than steam were included in the statistics for steam vessels, and therefore for purposes of comparison power vessels of 5 tons and over are combined with steam vessels in the statistics presented in Table 14. In Table 19 is shown the total value of steam and other power vessels launched, of iron and steel and of wooden construction, as reported at the last three censuses, with the per cent each class is of the total.

TABLE 19.—*Value of iron and steel and wooden steam and other power vessels of five tons and over launched by private shipyards, with per cent of total: 1890 to 1905.*

CLASS.	1905		1900		1890	
	Value.	Per cent of total.	Value.	Per cent of total.	Value.	Per cent of total.
Total	$66,029,538	100.0	$27,305,701	100.0	$18,866,068	100.0
Iron and steel vessels	62,932,880	95.3	24,311,343	89.0	11,014,646	65.3
Wooden vessels	3,096,658	4.7	2,994,358	11.0	5,851,422	34.7

During the fifteen years covered by the table there has been more than a fourfold increase in the value of power driven steel vessels launched, whereas the value of power driven wooden vessels launched has decreased during the period, and as a result the value of the latter class of vessels formed an insignificant proportion of the total value at the census of 1905.

Table 20 shows, by states, the number, tonnage, and value of vessels of 5 tons or over driven by power other than steam, launched during 1904.

TABLE 20.—*Number, gross and net tonnage, and value of power vessels other than steam, of five tons and over, launched during 1904 by private shipyards, by states.*

STATE.	Number.	TONNAGE.		Value.
		Gross.	Net.	
United States	[1]311	3,247	2,383	$479,168
California	76	464	362	111,600
Massachusetts	13	110	90	22,628
Minnesota	13	485	263	29,044
Mississippi	5	72	49	10,400
New Jersey	6	41	34	5,550
New York	64	706	532	147,075
Virginia	26	190	146	19,075
Wisconsin	49	347	313	33,170
All other states[2]	59	832	594	100,626

[1] Includes 4 vessels of 90 gross tonnage and 50 net tonnage, valued at $5,750, which were launched by establishments engaged primarily in the manufacture o. other products.

[2] Includes states as follows: Alabama, Connecticut, Kentucky, Louisiana, Maine, Maryland, Michigan, New Hampshire, North Carolina, Ohio, Pennsylvania, Rhode Island, Texas, Washington.

The 311 vessels of 5 tons or over, with motive power other than steam, launched in the United States at the census of 1905, had an average gross tonnage of not quite 10½ tons and an average value of about $1,541. In the construction of these vessels New York led in tonnage and value, but California launched the greatest number.

The wide variation in the average value per gross ton of the vessels in the different states is due to the different character and uses to which such vessels are now applied. Pleasure boats, built for high speed and luxuriously fitted, have become a feature of motor boat building, while boats for fishing and freighting are also being constructed with internal combustion engines. The clumsy and unreliable engines of this type built by individual mechanics or small boat building concerns a few years ago have now given place to the reliable and compact motors built by large establishments devoted entirely to their construction. The evolution of the high speed motor boat has resulted naturally from the improvements in hydrocarbon engines, and the standardization of the parts of this class of motors has done much to increase the use of larger boats of this type.

Barges.—Table 21 gives the value of barges as reported at the last three censuses, divided according to iron and steel or wooden construction, with the per cent each is of the total at each census period.

TABLE 21.—*Value of iron and steel and wooden barges, with per cent of total: 1890 to 1905.*

CLASS.	1905		1900		1890	
	Value.	Per cent of total.	Value.	Per cent of total.	Value.	Per cent of total.
Total	$3,722,069	100.0	$4,009,170	100.0	$1,773,186	100.0
Iron and steel barges	528,180	14.2	181,000	4.5	325,000	18.3
Wooden barges	3,193,889	85.8	3,828,170	95.5	1,448,186	81.7

There was an increase in steel barge construction at the census of 1905 over both the previous censuses, but the per cent of the total remains comparatively small. Wooden barges still form the larger proportion of this product. The decrease shown for 1905 as compared with 1900 may be attributed to the depression in the shipbuilding industry rather than a decline in the use of barges.

Floating dry docks, floating coal docks, and such minor products as rafts and scows constructed for a single trip at the end of which they were broken up and sold as lumber, were not included in this presentation. There are, however, a considerable number of sand and mud scows, coal boats and lighters, dredges, pile drivers, house boats, etc., included in the statistics for 1900 and 1905. At the census of 1905 there were 577 of these craft, built chiefly in Pennsylvania, with a total tonnage of 55,596 and value of $303,357. The total value of these is comparatively small, but in number and tonnage they form a considerable part of the products of this class.

Table 22 shows, by states, the number, tonnage, and value of barges of all classes as reported at the last two censuses.

TABLE 22.—*Number, gross and net tonnage, and value of barges, by states: 1905 and 1900.*

STATE.	Census.	Number.	TONNAGE. Gross.	TONNAGE. Net.	Value.
United States	1905	[1]1,244	277,310	266,853	$3,722,069
	1900	844	299,560	255,537	4,009,170

	1900	29	12,027	10,911	169,820
Mississippi	1905	13	1,955	1,570	34,500
	1900	8	1,150	946	22,310
New Jersey	1905	35	19,605	19,481	379,841
	1900	41	42,967	37,778	386,606
New York	1905	185	79,094	75,618	941,666
	1900	175	65,602	51,196	1,008,664
Ohio	1905	41	3,434	3,245	114,025
	1900	36	9,640	8,610	120,000
Pennsylvania	1905	573	76,102	75,750	340,807
	1900	174	65,880	65,328	125,060
Virginia	1905	12	2,280	2,215	31,350
	1900	4	400	360	4,000
Washington	1905	34	4,437	3,816	92,740
	1900	116	2,478	2,183	75,916
All other states	[2]1905	114	43,975	41,457	1,131,054
	[3]1900	176	86,952	67,389	1,853,818

[1] Includes 124 barges of 21,770 gross tonnage and 21,690 net tonnage, valued at $323,468, built by establishments engaged primarily in the manufacture of other products.
[2] Includes states as follows: Alabama, Connecticut, Delaware, District of Columbia, Indiana, Iowa, Maine, Massachusetts, Minnesota, Missouri, New Hampshire, North Carolina, Oregon, Rhode Island, South Carolina, Texas, West Virginia, Wisconsin.
[3] Includes states as follows: Alabama, Arkansas, Connecticut, Delaware, District of Columbia, Georgia, Indiana, Iowa, Maine, Massachusetts, Michigan, Minnesota, Missouri, Oregon, Texas, West Virginia, Wisconsin.

The principal state in barge construction at the census of 1905 was New York, with Maryland second. Although Pennsylvania reported the greatest number of this kind of craft, the major proportion was scows, coal boats, etc. New Jersey, the third state in the building of barges for 1905, was second to New York for 1900.

Sail vessels.—The building of sail vessels of 5 tons and over is decreasing, as is evident from Tables 23 and 24. The first of these presents the statistics of sail vessels launched for the last three censuses according to iron and steel or wooden construction. with the per cent each is of the total.

TABLE 23.—*Value of iron and steel and wooden sail vessels of five tons and over launched by private shipyards, with per cent of total: 1890 to 1905.*

CLASS.	1905 Value.	1905 Per cent.	1900 Value.	1900 Per cent.	1890 Value.	1890 Per cent.
Total	$3,620,119	100.0	$4,210,228	100.0	$5,340,941	100.0
Iron and steel vessels	221,900	6.1	962,600	22.9	211,200	4.0
Wooden vessels	3,398,219	93.9	3,247,628	77.1	5,129,741	96.0

The above statistics show less steel vessel building for 1905 than for 1900. In the latter year one establishment on Lake Michigan built 3 steel sail vessels, aggregating 15,117 tons and valued at over $500,000, whereas the same establishment did not report any sail vessels launched in 1904. The value reported for wooden sail vessels of 5 tons and over launched during 1904 was slightly in advance of that for 1900, but considerably less than for 1890. The following table presents the number, tonnage, and value of sail vessels, by states, as reported at the last two censuses:

TABLE 24.—*Number, gross and net tonnage and value of sail vessels of five tons and over launched by private shipyards, by states: 1905 and 1900.*

STATE.	Census.	Number.	TONNAGE. Gross.	TONNAGE. Net.	Value.
United States	1905	349	64,615	55,074	$3,620,119
	1900	648	80,294	70,120	4,210,228
California	1905	16	1,116	1,021	65,277
	1900	22	8,256	7,530	560,860
Connecticut	1905	9	3,106	2,589	204,762
	1900	14	188	180	18,500
Maine	1905	77	38,692	32,461	2,050,783
	1900	76	32,651	28,100	1,500,301
Maryland	1905	4	384	268	29,000
	1900	20	374	220	20,450
Massachusetts	1905	49	4,280	2,994	297,875
	1900	128	3,889	2,910	384,000
Mississippi	1905	14	280	197	29,150
	1900	14	193	140	12,800
New Jersey	1905	26	880	761	86,800
	1900	80	357	240	25,695
New York	1905	34	5,146	4,924	287,900
	1900	85	1,400	1,150	139,697
North Carolina	1905	4	70	55	4,125
	1900	9	142	109	6,225
All other states	[1]1905	116	10,661	9,804	564,447
	[2]1900	200	32,844	29,541	1,541,700

[1] Includes states as follows: Alabama, Delaware, Florida, Illinois, Louisiana, Michigan, Missouri, Rhode Island, Virginia, Washington, Wisconsin.
[2] Includes states as follows: Alabama, Delaware, Florida, Georgia, Illinois, Kentucky, Louisiana, Michigan, Minnesota, Missouri, Ohio, Oregon, Pennsylvania, Rhode Island, South Carolina, Texas, Virginia, Washington.

The state of Maine reported considerably more than one-half the total tonnage and value of sail vessels launched in the United States during 1904. A noteworthy increase is shown both in tonnage and value of sail vessels built in this state. Massachusetts, the second state in rank, shows an increased tonnage, but a decrease in value reported for sail vessels.

The falling off in the tonnage and value of the sail vessels included in "all other states" was caused by the decrease in the building of vessels of this type on the Great Lakes. As explained in the paragraph above in connection with Table 23, one establishment on Lake Michigan accounted for about one-half of the decrease.

Canal boats.—Canal boat building has fallen off materially, as is shown in Table 14. The decrease since 1880 in both the number and value of canal boats built is there seen to have been over 50 per cent at each census period. All of the canal boats reported during 1904 were constructed of wood, although 6 steel canal

boats were built in the year following. In Table 25 the number, tonnage, and value of canal boats built are given by states as reported in 1900 and 1905.

TABLE 25.—*Number, gross and net tonnage, and value of canal boats, by states: 1905 and 1900.*

STATE.	Census.	Number.	TONNAGE.		Value.
			Gross.	Net.	
United States	1905	30	5,613	5,408	$99,300
	1900	70	20,994	19,509	225,374
New York	1905	26	5,217	5,076	83,100
	1900	32	6,909	5,499	82,850
All other states	[1] 1905	4	396	332	16,200
	[2] 1900	38	14,085	14,010	142,524

[1] Includes states as follows: Louisiana, Maryland.
[2] Includes states as follows: Connecticut, Illinois, Maryland, New Jersey, Ohio, Pennsylvania.

Inasmuch as there were but 4 small canal boats reported by other states during the census year, New York is the only state that can be separately reported for the census of 1905. In addition to these, a few may have been built by boat builders or by canal transportation companies.

The canal boat is built to carry the greatest possible cargo with a minimum draft. Although intended primarily for use on canals, some of them appear on rivers and lakes, as in the case of the canal boats of the Erie canal, which often receive their cargo at New York city, and are towed up the Hudson river, through the canal to their destination, which may be Buffalo or some other lake port.

Small boats.—Included under this head are all vessels of less than 5 gross tons built by establishments reporting a product of $500 or over during the census year. All classes of small power and sailboats, rowboats, and canoes are represented in the statistics given; but, as this class of construction is often done by carpenters or other individuals who are not regularly engaged in the work, it is probable that there was actually a considerably greater aggregate than is shown. However, as may be deduced from Table 4, there was an increase of 52.4 per cent in the value reported for 1905 over that shown for 1900, an increase of 41.4 per cent from 1890 to 1900, and an increase of 58.7 per cent from 1880 to 1890, which shows the steady advance in this manufacture. Table 26 shows for 1900 and 1905, by states, the number and value of small boats manufactured, under two heads, namely, "small power boats" and "rowboats, canoes, and small sailboats."

The difference between the total value as reported in Table 26 for 1905 and the amount shown in Table 4, $147,542, represents the value of small boats reported by establishments engaged primarily in the manufacture of other products. An increase is shown in 1905, as compared with 1900, in the manufacture of small power boats and in the aggregate reported for rowboats, canoes, and small sailboats, both as to total number and total value.

TABLE 26.—*Number and value of boats under five tons, by states: 1905 and 1900.*

STATE.	Census.	Total value.	SMALL POWER BOATS.		ROWBOATS, CANOES, AND SMALL SAILBOATS.	
			Number.	Value.	Number.	Value.

All other states	[3] 1905	159,813	147	103,194	1,745	56,619
	[4] 1900	107,032	97	56,108	1,146	50,924

[1] Includes 272 boats, valued at $102,527, made by establishments engaged primarily in the manufacture of other products.
[2] Includes 474 boats, valued at $45,015, made by establishments engaged primarily in the manufacture of other products.
[3] Includes states as follows: Alabama, Delaware, District of Columbia, Georgia, Idaho, Indiana, Kentucky, Mississippi, Missouri, North Carolina, Oregon, South Carolina, Tennessee, Texas.
[4] Includes states as follows: Arkansas, Delaware, District of Columbia, Idaho, Indiana, Kentucky, Mississippi, Missouri, North Carolina, Oregon, Tennessee, Texas, Vermont.

New York was the leading state in this construction at both censuses, reporting about one-fifth of the total value of small boats in 1905 and about one-third in 1900. A slight decrease is seen to have taken place during the five-year period in the value reported for both classes of small boats constructed in this state. Michigan and Massachusetts, the second and third

states, respectively, in small boat building, as reported for both 1905 and 1900, show a considerable increase for the intervening period. Maine, Minnesota, New Jersey, California, Connecticut, and Ohio rank from fourth to ninth, in the order named, all outranking Wisconsin, which has dropped from fourth place in 1900 to tenth in 1905.

Repair work.—The statistics concerning the value of repair work done by shipbuilding establishments show that such work is a prominent feature in the industry. As may be seen from Table 4, 27.6 per cent of the total value of products reported by the private shipyards of the United States during 1904 was for repairs. Table 27 gives the value of repair operations reported by iron and steel and wooden shipbuilding plants, including Government establishments, at the censuses of 1900 and 1905, with the per cent the repairs done in each kind of establishment were of the total and the per cent of increase during the five-year period.

TABLE 27.—*Value of repair work reported by private and Government shipyards, with per cent of total and per cent of increase: 1905 and 1900.*

	1905		1900		Per cent of increase.
	Value.	Per cent of total.	Value.	Per cent of total.	
Total	$32,466,751	100.0	$29,604,674	100.0	9.7
Private shipyards:					
Iron and steel	12,191,854	37.5	12,302,960	41.6	[1] 0.9
Wooden	10,637,186	32.8	10,831,476	36.6	[1] 1.8
Government shipyards	9,637,711	29.7	6,470,238	21.8	49.0

[1] Decrease.

The value of repairs reported by private shipyards decreased somewhat in the five years intervening between the two censuses, but the value of repairs reported by Government establishments is seen to have increased materially during the same period. These conditions indicate that an increasingly large proportion of repairs on naval vessels, which is now a considerable item in the aggregate value of repair work, is done in Government yards. Taken together, the amount of repairs reported by private shipyards and Government establishments shows an increase of $2,862,077 during the period. In Table 28 the value of repair operations by private shipyards is shown by states, as reported at the last three censuses.

New York was the leading state in this class of work at the three censuses shown in Table 28, and in 1905 reported nearly three times the value shown for New Jersey, the second state in rank at this census. New York shows an increase of 38.5 per cent from 1900 to 1905, while New Jersey reports an increase of but 1.1 per cent during the same period. California, the third state in rank in this class of work, shows a decrease of 7.1 per cent in 1905 as compared with 1900. Pennsylvania was second in 1900, but on account of a decrease of 35.1 per cent was passed in 1905 by both New Jersey and California, and occupied fourth place at the latter census. Ohio, Virginia, and Maryland were respectively fifth, sixth, and seventh in rank in the value of repairs reported at the census of 1905.

TABLE 28.—*Value of repair work reported by private shipyards, by states: 1890 to 1905.*

STATE.	1905	1900	1890 [1]

[1] Includes $500,848 reported by governmental establishments not reported separately by states.

[2] Includes states as follows: 1905—Alabama, District of Columbia, Georgia, Idaho, Indiana, Kentucky, Louisiana, Missouri, New Hampshire, South Carolina, Tennessee, Texas. 1900—Alabama, Arkansas, District of Columbia, Idaho, Indiana, Kentucky, Louisiana, Missouri, New Hampshire, South Carolina, Tennessee, Texas, Vermont, West Virginia. 1890—Alabama, Arkansas, District of Columbia, Georgia, Indiana, Kentucky, Louisiana, Missouri, New Hampshire, South Carolina, Tennessee, Texas.

EQUIPMENT OF SHIPYARDS.

Intimately connected with the repair work of a shipyard is the dry dock and marine railway equipment. Table 29 shows, by states, for 1905 the number of establishments thus equipped in comparison with the total number for continental United States, and the value of repair operations in establishments having dry dock or marine railway equipment in comparison with the total for repair work in each state.

The 388 private yards in the United States which have dry dock or marine railway equipment form only 35.4 per cent of the total number of shipbuilding and repair establishments, but they are credited with 77.3 per cent of the total value of ship repairs reported by all establishments. New York, the leading state in ship repair operations, shows the largest number of establishments having dry dock or marine railway equipment. Establishments having these facilities, therefore, do the bulk of the repair work.

TABLE 29.—*Number of private shipyards and value of repair work, together with number of private shipyards reporting dry dock or marine railway equipment and value of their repair work: 1905.*

All other states[1]	76	34	808,111	674,140

[1] Includes establishments distributed as follows: Alabama, 7; District of Columbia, 3; Georgia, 2; Idaho, 3; Indiana, 10; Kentucky, 9; Louisiana, 20; Missouri, 6; New Hampshire, 5; South Carolina, 1; Tennessee, 2; Texas, 8.

Dry docks.—In Table 30 is shown the number of dry docks, both private and Government, classified according to kind and dimensions—length of floor, width at entrance, and depth on sill—by states and geographic divisions.

As shown in Table 30, about two-thirds of the dry docks of the United States are in the North Atlantic states, New York alone reporting over one-third of the total number. Of the 62 dry docks reported in New York state, 57 are over 100 feet long in floor measurement, and 14 of these measure over 300 feet; 26 measure over 50 feet in width at entrance, 7 of these over 75 feet in width and over 20 feet in depth of sill, dimensions sufficient to accommodate the largest vessels.

New Jersey, the second state in importance with respect to dry dock equipment, shows as many dry docks as the entire North Central division. All of the 23 are over 100 feet in floor length, and 2 of them measure over 300 feet. Twelve of the dry docks in this state have a width at entrance of over 50 feet, and 20 have a depth on the sill of more than 10 feet. The remaining states in the North Atlantic group report 17 dry docks, 13 of which are over 100 feet in floor length and 5 are over 20 feet in depth of sill, while only 2 have a width at entrance exceeding 75 feet.

FLOATING DRY DOCK, DEWEY.

Of the 18 dry docks reported in the South Atlantic division, 8 were stationary; 4 of these, all in the state of Virginia, had a length of floor of over 300 feet, a width at entrance of more than 50 feet, and a depth on the sill of over 20 feet. Maryland has 2 large stationary dry docks, Delaware 1, and Florida 1. Four of the floating dry docks in the South Atlantic division were in Maryland, 3 in West Virginia, and 3 in Florida.

Of the 23 docks reported in the North Central division, only 2 have a width at entrance of more than 75 feet, and none exceed 20 feet in depth of sill, but 14 are over 300 feet in length of floor. Wisconsin has 4 stationary and 5 floating docks, but Ohio reports 6 large stationary dry docks, all of which are over 300 feet in length of floor. Illinois and Michigan each have 2 stationary dry docks with a floor length of over 300 feet.

The Western division has 4 dry docks with floor length of over 300 feet, a width at entrance of over 75 feet, and a depth on the sill of over 20 feet. Two of these are in Washington and 2 in California. The South Central division has 2 floating dry docks of more than 300 feet of floor length, 1 of which is in Alabama and the other in Louisiana.

The statistics presented in Table 30 are for the year 1904 and include 15 Government dry docks reported by the naval stations, shown in the following tabular statement:

Number and kind of dry docks at each naval station in the United States: 1905.

NAVAL STATION.	Stationary.	Floating.
Total	11	4
Mare Island	1	.....
Pensacola	.....	2
Portsmouth	1	1
Boston	2	.....
Brooklyn	3	.....
League Island	1	.....
Norfolk	2	.....
Puget Sound	1	.....
New Orleans	.....	1

In addition to the dry docks included in the above statement, graving docks were under construction during 1904 at the naval stations at League Island, Pa.; Norfolk, Va.; Charleston, S. C.; and Mare Island, California.

The building of a floating dry dock is an extensive piece of work, and, while this work is not designated as vessel construction, its value for 1905 appears in this report under the head of "all other products." The most important construction of this kind during 1903 and 1904 was the building of the self-docking steel floating dry dock *Dewey* for the naval station in the Philippine Islands.

The *Dewey* is capable of lifting about 20,000 tons, which is considerably more than the weight of any vessel now in the United States Navy. The difficult feat of towing this enormous dry dock 14,000 miles from the shipyard to Subig bay, Philippine Islands, has been safely accomplished since the compilation of these statistics, and it may now be added to the list of available docks of the United States Government.

Marine railways.—Table 31 presents the number and total lifting capacity of the marine railways of the United States, by states and geographic divisions, and also the number of railways, classified by dimensions and lifting capacity. There was 1 Government marine railway at the Norfolk navy yard which is included in the table. There were also 5 Government railways, 1 of which was situated at Washington, D. C., 1 at San Juan, Porto Rico, and 3 at Cavite, Philippine Islands, which are not included in this list, as these stations were not reported as being engaged in ship construction and repairs.

Table 31 shows that more than one-half the total number of marine railways of the United States are located in the North Atlantic states. New York alone reported about one-fourth of the total number. Of the New York marine railways, 31 have a cradle length exceeding 100 feet, 33 a cradle breadth exceeding 25 feet, and 11 have a lifting capacity exceeding 500 tons. New Jersey is the second state in rank of the North Atlantic states according to the total lifting capacity represented by marine railways, although Connecticut and Massachusetts both report a greater number. Of the 24 marine railways reported in New Jersey, 12 have a cradle length of more than 100 feet and 10 have a cradle breadth exceeding 25 feet, while 5 have a lifting capacity of 500 tons. Eight of the marine railways reported in Connecticut have a cradle length of more than 100 feet, 9 a cradle breadth exceeding 25 feet, and 7 a lifting capacity of 500 tons or over.

Following the 3 states above mentioned, in the order of their importance among the North Atlantic states in tons of lifting capacity represented in marine railway equipment, are Maine, Massachusetts, Pennsylvania, and Rhode Island. In these states there are 6 railways with cradles more than 200 feet in length, 36 railways with cradles exceeding 25 feet in breadth, and 16 railways with a lifting capacity of 500 tons and over.

TABLE 31.—NUMBER AND LIFTING CAPACITY OF MARINE RAILWAYS, CLASSIFIED ACCORDING TO DIMENSIONS AND LIFTING CAPACITY, BY STATES AND GEOGRAPHIC DIVISIONS: 1905.

STATE.	Total number.	Total lifting capacity (tons).	NUMBER OF MARINE RAILWAYS.

POWER.

The statistics regarding power used by private iron and steel and wooden shipbuilding establishments reported at the last two censuses are presented in Table 32.

TABLE 32.—*Number of private establishments reporting power owned or rented, and amount of each kind of power available for use, by branches: 1905 and 1900.*

Furnished to other establishments, horsepower	170	127	145	.....	25	127

Of the total number of shipbuilding establishments in the United States, 55.7 per cent reported the use of power in 1905 as compared with 38.2 per cent in 1900. All the iron and steel shipbuilding establishments and over one-half the wooden shipbuilding establishments reported power used, at the census of 1905. There was an absolute increase of 25,441 horsepower over the amount reported in 1900, which represents an increase of 50.1 per cent reported by iron and steel shipbuilding and repair plants, and of 14 per cent reported by wooden shipbuilding and repair establishments. There were 486 wooden shipbuilding and repair yards which were without power.

Of the total horsepower shown for the census of 1905 in Table 32, 74.2 per cent represents steam engines owned, an increase of 26.6 per cent in number and 24 per cent in horsepower over 1900. The use of gas engines is reported to have increased materially, while fewer water wheels are used. Electricity was reported to a much greater extent for 1905, as is shown in the increased number of electric motors reported, and by the heavy increase of 146.1 per cent in the electric horsepower reported. In fact, electricity has become essential to the equipment of a modern shipbuilding plant.

The detailed statistics of the shipbuilding industries are shown, by states, for 1905 in Tables 33 and 34. Table 33 is a summary of statistics for iron and steel shipbuilding, and Table 34 is a summary for wooden shipbuilding.

TABLE 33.—IRON AND STEEL SHIPBUILDING—DETAILED SUMMARY, BY STATES: 1905.

	United States.	Connecticut.	Maryland.	Michigan.	New Jersey.	New York.	Pennsylvania.	All other states.[1]
Number of establishments	54	4	3	5	6	10	5	21

THE STEAM AND STREET RAILROAD CAR INDUSTRY

THE STEAM AND STREET RAILROAD CAR INDUSTRY.

Previous to the present census, statistics for the construction and repair of street railroad cars have not been presented in a special report, although the operations of steam car manufacturers and the repair shops of steam railroads were treated in a special report entitled "Cars, Steam Railroad," which appeared in Part IV of the report on manufactures for the census of 1900. Since 1900 the growth in the building and repairing of street cars has been so remarkable that the industry has assumed proportions which entitle it to special treatment. Accordingly this report presents statistics for the manufacture and repair of street railroad cars as well as for the allied industries—the building of steam railroad cars and the work of steam railroad repair shops.

In connection with the statistics of repair work done by both street and steam railroad companies, it should be remembered that not all the value of products results from repairs upon cars. In the case of steam railroad repair shops this is especially true, since the value of repairs upon locomotives forms an item upon the reports of the railroads which nearly, if not quite, in many instances, equals the value of repairs performed upon cars. Thus the magnitude of the operations of steam railroad repair shops, which is indicated by the figures in the following pages, is due in part to the construction of and repairs on locomotives.

STEAM RAILROAD CARS AND REPAIRS.

The statistics presented for steam railroad cars and repairs show the operations of establishments classified under the heading "cars, steam railroad, not including operations of railroad companies," and "cars and general shop construction and repairs by steam railroad companies." For the sake of brevity these classifications will be denoted, respectively, as "cars, steam railroad" and "steam railroad repair shops."

In the following tables wherever horse, cable, or electric street cars are shown, they are products of secondary importance produced by plants engaged largely, and almost exclusively, in the manufacture of steam railroad cars. The figures for establishments engaged chiefly in the manufacture of street cars have been segregated and are shown in Table 17. Likewise the locomotives built in the motive power and machinery department of the railroad repair shops were secondary products, and they are included in the following tables. The report of the bridge and building department includes shop work only.

In the majority of cases the reports for the repair shops of steam railroad companies were expected to balance, namely, the value of products was to equal the expenses enumerated upon the schedules, and the few cases where this condition did not obtain were of minor importance and do not affect the value of the results.

Table 1 presents a comparative summary for the combined industry—cars, steam railroad, and steam railroad repair shops—for each census from 1890 to 1905.

TABLE 1.—*Cars, steam railroad, and steam railroad repair shops—comparative summary, with per cent of increase: 1890 to 1905.*

[1] Reduced from 1,361 to correct error in tabulation.
[2] Decrease.
[3] Includes proprietors and firm members with their salaries; number only reported in 1900 and 1905, but not included in this table.

At the census of 1890 the value of products of the combined industry was $199,545,435, which at the census of 1900 was increased by $109,203,022, or 54.7 per cent. At the census of 1905 the value of products was $421,038,809, which was an absolute increase over the total for 1900 of $112,290,352. These industries are large employers of labor and at the census of 1905 employed an average of 270,958 wage-earners during the census year, of which only 629 were women 16 years and over, and 129 were children under 16 years. For the entire period shown by the table the capital invested in the two industries practically doubled,

while the number of establishments increased only 54.3 per cent. The latter increase was not the result of uniformly progressive increases since 1890, but represents the net gain resulting from a large increase in number between 1890 and 1900 and a decrease from 1900 to 1905.

Table 2 presents statistics for the two industries separately for each census from 1890 to 1905.

[1] Decrease.
[2] Reduced from 1,296 to correct an error in tabulation.
[3] Includes proprietors and firm members with their salaries; number only reported in 1900 and 1905, but not included in this table.
[4] Not reported in full.

The table shows that for every statistical item presented the construction and repair work by steam railroad repair shops far exceeded in magnitude the operations of the manufacturers of steam railroad cars. At the census of 1905, 1,141, or 94 per cent, of the establishments in the combined industry were operated by steam railroad companies as repair shops, which represented an investment of $146,943,729, or 62.5 per cent of the total capital devoted to both industries. Of the wage-earners employed at this census, 236,900, or 87.4 per cent, were employed by steam railroads in construction and repair work.

Between 1900 and 1905 the number of repair shops decreased from 1,293 to 1,141, or 11.8 per cent; while the establishments engaged primarily in the manufacture of steam railroad cars increased from 65 to 73, or 12.3 per cent. The decrease in the number of repair shops is attributable largely to the introduction by the railroads of more economical methods of effecting repairs, which have resulted in the concentration of repair work in large repair shops. This concentrating movement is indicated by the figures, which show that at the census of 1905 the average investment in repair shops was $128,785, and the value of the average output was $271,571; whereas at the census of 1900 the averages for these items were, respectively, $92,483 and $168,784.

In the manufacture of steam railroad cars by establishments devoted principally to their construction, it is significant that the increase in the number of wage-earners for the entire period covered by the table was very much less than the increases in the cost of materials and value of products. Between 1900 and 1905 the last two items increased 22.5 and 22.8 per cent, respectively, or in nearly the same ratio, while the number of wage-earners increased only 1.8 per cent. This is due in part to the increased cost of materials, and to the fact that the average number of wage-earners was determined with more exactness at the census of 1905 and possibly resulted in a proportionately smaller number.

The table shows a slight decrease in the capital invested in the industry between 1900 and 1905, notwithstanding there was an increase in the number of establishments. This decrease in capital was due to the fact that during the census year 1904 one of the largest establishments in the country was practically idle, operating, on a limited scale only, the department producing steel forgings. According to the method of classification adopted by the Bureau of the Census, the nature of the products placed the entire establishment under the classification "iron and steel forgings," and the capital of several millions of dollars invested in the establishment was thus diverted from the class of cars, steam railroad, under which it was classified in 1900, when the establishment was operating normally. Thus, if this company had been operating upon a normal basis in 1904, there would have been a substantial gain instead of a slight loss in the capital invested in the industry at the census of 1905.

Products.—Table 3 shows the number and kind of steam railroad cars built at the censuses of 1900 and 1905, distributed according to the character of establishment in which they were constructed.

[1] Not reported separately.

At the census of 1905 there were 119,940 steam railroad cars, valued at $100,346,912, reported as completed during the census year, which represents a decrease of 25,497 in number and an increase of $13,205,394 in value, compared with the output reported at the census of 1900. The decrease in number was due to a marked falling off in the number of freight cars produced at the census of 1905, which was 27,639 less than the number reported in 1900. It is significant, however, that notwithstanding this decrease of 19.3 per cent in the number of freight cars, the value increased $1,974,628, indicating a remarkable increase in the average value per car. The production of passenger cars increased 1,077, or 78.7 per cent, in number and $11,676,228, or 132.6 per cent, in value, which also indicates a decided increase in the average value per car.

At the census of 1905 the steam railroad car manufacturing establishments reported 102,646 cars, valued at $87,289,248. These figures represent a decrease since 1900 of 14,923, or 12.7 per cent, in the number of cars built and a gain of $17,759,936, or 25.5 per cent, in the value of the output. In the case of the railroad repair shops there was also a decrease in the number of cars built amounting to 9,775, or 36.3 per cent, but this loss was accompanied by a decrease in value amounting to $3,523,351, or 21.3 per cent.

Of the total number of cars built in steam car manufacturing establishments at the census of 1905, 2,030 were passenger and 100,616 were freight cars. In the case of the former class of cars there was a gain since 1900 of 1,051, or 107.3 per cent, in number and $10,771,994, or 146.2 per cent, in value; while in the case of freight cars there was a loss of 15,974, or 13.7 per cent, in number and a gain of $6,987,942, or 11.2 per cent, in value. The steam railroad repair shops built 416 passenger and 14,742 freight cars during the census year 1905. The increases shown in the number and value of passenger cars produced by this class of establishments were comparatively small, whereas there were marked decreases in both the number and value of freight cars produced.

45254—MFG 1905—PT 4—08——25

Since 1900 the production of steel railroad cars for both passenger and freight service has increased rapidly, and the substitution of steel freight cars of large tonnage and of distinct types for smaller wooden cars of rather nondescript type is progressing on the majority of the railroads as fast as conditions permit. The changes in carrying capacity are shown by the reports of the Interstate Commerce Commission on the equipment of steam railroads. As recently as 1902 there were no freight cars reported by the railroads with a capacity of 200,000 pounds, but in 1905, 200 such cars were reported. The average capacity of the 1,727,620 freight cars reported by the railroads in 1905 was 62,000 pounds, whereas the same average for the 1,505,992 freight cars reported in 1902 was 56,000 pounds. Moreover, in 1902, 1,275,742, or 84.7 per cent of the total number of freight cars reported, had a capacity of 60,000 pounds or less; whereas for 1905, 1,271,154, or only 73.6 per cent of the total number of freight cars reported, had a capacity of 60,000 pounds or less.[1] These figures indicate the cause of the decrease in number and increase in value of freight cars shown in Table 3. The greater the capacity of the car the heavier and more substantial must be the construction, and consequently fewer cars are built, while the cost is increased. The extensive and growing use of steel in the construction of the cars has contributed to the same result. Thus the average value of the freight cars produced at the census of 1905 was $686, or $147 more than the average value per car in 1900. In accepting the average value per car it must be remembered that it is based upon the total of all kinds and sizes of cars. In the case of passenger cars changes of a similar nature have resulted in an increase since 1900 of $1,940, or 30.1 per cent, in the average value per car.

At the census of 1905 the average value of the passenger cars produced in railroad car manufacturing establishments was $8,936, or $3,297 more than the

[1] Interstate Commerce Commission, "Statistics of Railroads in the United States," 1902, page 29; ibid., 1905, page 29.

average value of the same class of cars produced in railroad repair shops. This difference is due in part to the fact that the value of the cars as reported by the railroad companies was not the selling price, but represented only the sum of the building expenses as they appeared upon the report, and in part to the fact that the railroads for the most part built only the lighter coaches intended for suburban traffic, whereas the costly diners, sleeping cars, and Pullman day coaches were constructed in steam car manufacturing establishments. The average value of the freight cars built in the latter class of establishments was $687, which was $8 higher than the average value per car built by the repair shops. The lowest average value, $439, for freight cars resulted from the building operations of the street car manufacturing establishments, and was due to the fact that among the 136 cars produced by them were a number of gondolas, or ore cars, and narrow gauge freight cars.

In Table 4 is presented in detail the value, and, wherever possible, the quantity of products of the combined industries at the censuses of 1900 and 1905, for the United States, for the 10 leading states, and for the remaining states and territories combined as "all other states."

[3] Number and value can not be shown separately.

[4] Includes value of locomotives.

[5] Includes value of passenger cars.

Three classes of products are distinguished in the table: First, those produced by the motive power and machinery department, consisting principally of the repairing and building of locomotives; second, those derived from the car department, for the most part cars built and repaired; and third, those resulting from the operations of the bridge and building department, consisting of shopwork only.

At the census of 1905 the value of the product of the car department of the combined industries was $260,956,745, which constituted 62 per cent of the aggregate value of the products of the three departments. Only 148 locomotives, valued at $1,853,939, were built in the motive power and machinery department, which, when compared with the 272 locomotives, valued at $3,276,393, reported as completed by this department at the census of 1900, indicates a decrease of 45.6 per cent in number and 43.4 in value for this class of products during the five years. The value of the repair work upon locomotives was $101,351,907, or $3,989,692 less than the value of the same class of work done in the car department upon passenger and freight cars. At the census of 1900 the value of repairs upon locomotives was $57,383,143, and the value of repair work upon passenger and freight cars was $74,665,500, so that the totals for 1905 for these items represent increases over the same items in 1900 of 76.6 and 41.1 per cent, respectively. The repair work shown in the table was all reported by railroad repair shops, and thus, at the census of 1905, the aggregate value of the repairs performed by steam railroads upon their rolling stock was $206,693,506, which, since the expenses and the value of product as returned upon the reports of the railroad companies balanced in the great majority of cases, is equivalent to stating that this amount represents approximately the total cost to the railroad companies of repairs of this nature. The value of products of the bridge and building department was of comparatively small importance, amounting to but $5,103,186, or only 1.2 per cent of the value of all products.

Of the 10 leading states, Pennsylvania, with a product valued at $80,449,604 at the census of 1905 and $62,326,081 at the census of 1900, stood considerably in the lead in the combined industries at both periods, while at the census of 1905 Illinois was second, Ohio, third, and Indiana fourth. At the census of 1905 the aggregate value of products for these 4 states constituted 44.7 per cent of the total value of products for the combined industries for the United States. In the motive power and machinery department the value of the output for the state of Pennsylvania was by far the greatest, amounting to $32,462,711, or three times the value of products of the state of Illinois, which ranked next in this respect. These 2 states also led with respect to the value of products resulting from the operations of the car department of the combined industries, Pennsylvania again taking first place, with products valued at $47,216,130, and Illinois second, with products valued at $45,811,429. With respect to the number of cars built, both passenger and freight, however, Illinois was considerably ahead of any state. In the manufacture of passenger cars Ohio ranked second, building 382 cars, or about one-half the number turned out in Illinois. In the manufacture of freight cars Pennsylvania came next to the leading state, producing 21,347 freight cars, or 5,790 fewer than Illinois. The average value of the freight cars built in Pennsylvania, however, was $862, whereas in Illinois those built during the census year had, on the average, a value of only $686.

This difference between the 2 states in the average value per car is explained by the fact that in Pennsylvania the production of steel freight cars of great capacity is increasing rapidly, and in no other state has this modern class of freight cars been built in such numbers. Thus the average value per freight car built in Pennsylvania was considerably greater than that for cars of the kind produced in any of the states in which freight car building operations were at all extensive. Of the 10 states shown in the table, 6 produced over 5,000 freight cars, and the average value per car produced by each of these states was as follows: Pennsylvania, $862; Missouri, $755; Illinois, $686; Indiana, $652; Michigan, $639; and Ohio, $349. The average value, then, at the census of 1905 of the freight cars built in Pennsylvania was $107 more than the average value of cars built in Missouri, the state which returned the second largest average.

CARS, STEAM RAILROAD.

Table 5 is a summary, by geographic divisions, of the statistics returned in 1905 for cars, steam railroad.

TABLE 5.—CARS, STEAM RAILROAD—SUMMARY, BY GEOGRAPHIC DIVISIONS: 1905.

DIVISION.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
			Number.	Salaries.	Average number.	Wages.			
United States	73	$88,179,047	2,303	$2,854,690	34,058	$20,247,821	$5,198,831	$75,657,126	$111,175,310
North Atlantic [1]	20	41,057,506	846	1,197,613	8,472	4,827,879	1,763,698	19,631,217	28,443,177
South Atlantic [2]	7	5,890,732	184	214,240	3,180	1,703,222	303,754	4,947,458	7,899,356
North Central [3]	40	39,583,640	1,177	1,363,249	21,658	13,269,534	3,067,728	49,648,942	72,724,460
South Central [4]	6	1,047,169	96	79,588	748	447,186	63,651	1,429,509	2,108,317

[1] Includes New Hampshire, Massachusetts, New York, New Jersey, Pennsylvania.
[2] Includes Delaware, Maryland, West Virginia, Georgia.
[3] Includes Ohio, Indiana, Illinois, Michigan, Wisconsin, Iowa, Missouri, Kansas.
[4] Includes Kentucky, Tennessee, Alabama, and 1 establishment for Colorado in the Western division.

The table shows that the North Central division led in every statistical item with the exception of capital. In fact, this division reported 65.4 per cent of the value of products of the industry and employed 63.6 per cent of the total number of wage-earners. The North Atlantic division, with one-half as many establishments and $2,073,866 more capital than the leading division, shows a product valued at only slightly over one-third as much as that of the latter. This inconsistency in the capital invested and value of products is explained in connection with Table 6, in which the returns for Pennsylvania and Illinois will be found to be responsible for this discrepancy in the statistics of the two leading geographic divisions.

Table 6 is a comparative summary showing the statistics for the manufacture of steam railroad cars exclusive of the operations of steam railroad companies, distributed according to the leading states in this branch of the industry, for each census from 1890 to 1905.

TABLE 6.—CARS, STEAM RAILROAD—COMPARATIVE SUMMARY, BY STATES: 1890 TO 1905.

STATE.	Census.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.

[1] Includes proprietors and firm members with their salaries; number only reported in 1900 and 1905, but not included in this table.
[2] Included in "all other states" in 1900 and 1890.
[3] Includes establishments distributed as follows: Alabama, 2; Colorado, 1; Georgia, 2; Iowa, 1; Kansas, 1; Kentucky, 1; Maryland, 1; New Hampshire, 1; New Jersey, 2; Tennessee, 2; West Virginia, 1; Wisconsin, 2.
[4] Includes establishments distributed as follows: Alabama, 2; Georgia, 2; Kentucky, 1; Maryland, 1; Massachusetts, 2; New Hampshire, 1; New Jersey, 2; Tennessee, 1; West Virginia, 1.
[5] Includes establishments distributed as follows: Alabama, 3; California, 1; Florida, 1; Kansas, 2; Kentucky, 2; Massachusetts, 3; Minnesota, 2; New Hampshire, 1; North Carolina, 1; Tennessee, 2; Virginia, 1; West Virginia, 1.

Illinois held first rank in the manufacture of steam railroad cars by establishments not operated by railroad companies during the entire period covered by the table. The value of products for this state in 1905 was $30,926,464, which represented a gain since 1890 of $13,809,241, or 80.7 per cent, and constituted 27.8 per cent of the total value of the products of the industry in the United States. Michigan ranked next to Illinois in 1890, but relinquished this position to Pennsylvania in 1900, and has since occupied third place. In 1905 these 3 states reported aggregate products of a value of $63,822,445, or 57.4 per cent of the total for the country.

There was no material change in the total number of establishments engaged in this branch of the industry in the United States at the three census periods, although Illinois increased from 9 establishments in 1890 to 16 in 1905, and Pennsylvania decreased from 15 in 1890 to 9 in 1905. These were the only states showing a change of more than 3 establishments in 1905 as compared with 1890.

The industry has been practically at a standstill in the state of Delaware since 1890, the increase in value of products amounting to but 9.4 per cent for the fifteen years. Measured by the same standard, Pennsylvania has made slight progress in the industry during

the past five years, and in New York the industry has not even held its own, the value of the output falling off $977,539, or 18.7 per cent since 1900. Illinois is the only state which shows an increase of more than $5,000,000 for 1905, as compared with 1900, while increases of less than $5,000,000 and more than $1,000,000 are shown for Missouri, Michigan, Ohio, and Indiana. For 1900, as compared with 1890, increases of more than $5,000,000 each are shown for Pennsylvania and Illinois, and increases between $1,000,000 and $4,000,000 each for Missouri, New York, and Indiana.

Although at the census of 1905 Illinois produced an output valued at about half again as much as that of the state of Pennsylvania, yet the capital invested in the industry in the former state was not one-half as great as that invested in the industry in the latter state. This discrepancy was due in part to the inclusion of a class of assets in the capital of one of the large establishments in the state of Pennsylvania which were not included in the reports on capital of the large establishments located in Illinois. Owing to this difference in the returns of capital the relative importance of the 2 states in this industry is indicated more accurately perhaps by the number of persons employed and the value of the product. In this connection, however, it should be remembered that in the case of Illinois in the neighborhood of a third of the value of products was made up of the value of passenger cars, whereas comparatively few cars of this character were produced by establishments located in Pennsylvania, the principal production of which consists of freight cars. The prosperous condition of the manufacture of passenger cars, which is indicated by the increase in this class of cars, compared with the rather depressed condition of the freight car industry, which is indicated by the decrease in number and comparatively slight increase in value shown in Table 7 for this class of cars, gives to Illinois an apparent lead in the industry, which probably would not be so marked if the conditions for the manufacture of freight cars in Pennsylvania had been more favorable, or even upon a normal basis. In fact, it has already been pointed out that one of the largest establishments in the country, located in Pennsylvania, devoted normally to the production of this class of cars, produced none during the census year. In weighing the relative ranks of the 2 states, therefore, these conditions should be taken into account. In this case at least it is probable that the value of products fails to reflect accurately the true importance in this industry which belongs to the state of Pennsylvania under normal trade conditions.

Products.—In Table 7 is presented the total number and value of cars built by establishments classified under the industry, distributed according to kind, at the censuses of 1900 and 1905.

TABLE 7.—*Cars, steam railroad—number and value of cars built, distributed according to kind: 1905 and 1900.*

KIND.	1905	1900
Total number of cars built	103,064	118,504
Total value	$88,283,902	$70,620,166
Passenger service:		
Total number	2,030	979
Total value	$18,140,293	$7,368,299
Baggage and express—		
Number	199	72
Value	$896,185	$238,554
Chair and coach—		
Number	769	181
Value	$5,819,034	$957,526
Dining and buffet—		
Number	58	37
Value	$886,305	$404,503
Mail—		
Number	95	42
Value	$576,230	$197,465
Parlor—		
Number	114	37
Value	$1,686,417	$272,403
Passenger—		
Number	428	331
Value	$2,955,517	$1,975,469
Private—		
Number	13	11
Value	$211,658	$154,709
Sleeping—		
Number	304	194
Value	$4,775,624	$2,767,061
Other varieties—		
Number	50	74
Value	$333,323	$400,609
Freight service:		
Total number	100,616	116,590
Total value	$69,148,955	$62,161,013
Box—		
Number	38,184	47,338
Value	$28,508,632	$26,562,893
Coal and coke—		
Number	27,998	28,857
Value	$21,367,218	$18,414,718
Flat—		
Number	5,412	4,525
Value	$2,893,154	$1,923,525
Fruit—		
Number	2,840	1,620
Value	$1,727,771	$965,354
Furniture—		
Number	801	1,717
Value	$505,000	$1,148,265
Gondola—		
Number	9,518	11,821
Value	$5,518,084	$6,873,145
Refrigerator—		
Number	3,353	2,354
Value	$3,042,835	$1,956,097
Stock—		
Number	4,235	2,760
Value	$2,453,123	$1,426,800
Caboose—		
Number	160	193
Value	$150,977	$184,865
Other varieties—		
Number	8,115	14,905
Value	$2,982,161	$3,005,351
Street cars:		
Total number	418	935
Total value	$994,654	$1,090,854
Electric—		
Number	414	902
Value	$991,149	$1,062,172
Closed—		
Number	308	487
Value	$875,608	$993,143
Combination—		
Number	15	44
Value	$48,164	$68,320
Open—		
Number	8	371

Number	83	.....
Value	$60,358	.....
Horse—		
Number	4	[1]33
Value	$3,505	[1]$28,682

[1] Includes 25 cable cars, valued at $21,232.

Of the passenger service cars produced by this industry at the census of 1905, 769, or 38 per cent, were chair and coach cars, whose value constituted 32.1 per cent of the total value of all passenger service cars constructed. At the census of 1900 the number of ordinary passenger cars built formed the largest proportion of the total number, but during the succeed-

ing five years the production of chair and coach cars quadrupled, outstripping the production of ordinary passenger cars. The average value of each variety of passenger cars shown has increased since 1900.

At both censuses the most important varieties of freight service cars, from the standpoint of number and value, were the common box cars and the coal and coke cars. Both these classes showed decreases in number and increases in value, which resulted in an average value in the case of box cars of $747 at the census of 1905, compared with an average value of $555 at the census of 1900, and an average value in the case of coal and coke cars of $763 for 1905 and $638 for 1900.

The growth in construction of freight cars for special purposes is shown by the table. At the census of 1900, 1,620 fruit cars, valued at $665,354, were built, which increased to 2,840 cars, valued at $1,727,771, at the census of 1905. The output of refrigerator cars increased 999 in number and $1,086,738 in value, and stock cars 1,475 in number and $1,026,323 in value.

The production of street cars in establishments engaged primarily in the construction of steam railroad cars is apparently decreasing, as the number of street cars produced by them fell off more than one-half during the five years between 1900 and 1905, and the value also decreased, although not to so marked an extent as the number.

Exports.—Table 8 shows by countries the value of exports of passenger and freight cars, and parts of cars, for steam railroads, at each census period from 1880 to 1905.

TABLE 8.—*Value of exports of steam railroad passenger and freight cars, and parts of same, by countries: 1880 to 1905.*[1]

[1] Bureau of Statistics, Department of Commerce and Labor, "Commerce and Navigation of the United States."

[2] Not reported separately.

The value of the exports of steam cars decreased $623,971, or 24.4 per cent, from 1900 to 1905. There was a decided decrease in exports to the United Kingdom, France, and Germany, and to Canada and Mexico. On the other hand, the export trade in this class of commodities to certain countries shows substantial increases for the half decade: That to Japan increased $207,563; that to Argentina, $431,190; and that to Peru, $38,238. The Philippine Islands appear in the table for the first time in 1905.

STEAM RAILROAD REPAIR SHOPS.

Table 9 is a summary, by geographic divisions, of the statistics for steam railroad repair shops at the census of 1905.

TABLE 9.—STEAM RAILROAD REPAIR SHOPS—SUMMARY, BY GEOGRAPHIC DIVISIONS: 1905.

DIVISION.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
			Number.	Salaries.	Average number.	Wages.			
United States	1,141	$146,943,729	13,337	$11,931,996	236,900	$142,188,336	$4,821,710	$151,140,250	$309,863,499
North Atlantic[1]	270	54,272,332	4,073	3,357,678	70,616	42,199,050	1,800,116	51,056,924	98,319,747
South Atlantic[2]	135	11,008,934	1,370	1,175,305	27,558	14,373,361	381,841	14,240,549	30,202,383
North Central[3]	441	54,794,034	5,342	4,607,657	86,018	51,853,930	1,441,768	55,669,521	113,403,073
South Central[4]	153	14,661,078	1,532	1,580,033	31,765	18,190,402	513,979	18,037,823	38,336,404
Western[5]	142	12,207,351	1,020	1,211,320	20,943	15,571,593	684,006	12,135,433	29,601,892

[1] Includes Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania.
[2] Includes Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida.
[3] Includes Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas.
[4] Includes Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Arkansas, Indian Territory, Oklahoma, Texas.
[5] Includes Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Washington, Oregon, California, Alaska.

The North Central division ranked first in this branch of the industry as regards all the principal items except miscellaneous expenses. Of the totals for the United States, this division reported 38.7 per cent of the establishments, 37.3 per cent of the capital, and 36.6 per cent of the products. The North Atlantic division ranked second in all the principal items, except miscellaneous expenses, in which item it was first. The two leading divisions were of much greater importance than the remaining three shown in the table, the total value of the output of both being $211,722,820, or 68.3 per cent of the aggregate for the United States in this industry. Although the North Central division produced a product valued at $113,403,073, or $15,083,326 more than the North Atlantic division, yet the operations of the average establishment in the latter division were conducted on a much larger scale than those of the average repair shop in the former division. This greater concentration in the latter division is shown by the fact that the capital invested in and the value of the output of the establishments in this division were, respectively, $201,009 and $364,147, whereas the same averages for the leading division were only $124,249 and $257,150, respectively.

Table 10 is a comparative summary of the statistics of the industry, by states and territories, for each census from 1890 to 1905.

TABLE 10.—STEAM RAILROAD REPAIR SHOPS—COMPARATIVE SUMMARY, BY STATES AND TERRITORIES: 1890 TO 1905.

[1] Not reported.
[2] Included in "all other states" in 1890.
[3] Includes establishments distributed as follows: Alaska, 1; Oklahoma, 2; Rhode Island, 1.
[4] Includes establishments distributed as follows: Indian Territory, 2; North Dakota, 2; Rhode Island, 2; South Dakota, 2; Utah, 2; Wyoming, 1.

There were 7 states in 1905 that reported a value of products greater than $10,000,000. These states, arranged in order of value of products reported, are: Pennsylvania, Illinois, Ohio, New York, Indiana, Kansas, and Texas. Their total value of products amounted to $162,335,910, or 52.4 per cent of the total for the United States. The repair shops located in Pennsylvania performed repairs and construction work valued at $61,021,374, which was more than double the value of the work done by the repair shops located in the second state, Illinois.

Decided gains in output were reported in 1905 by all of the states except Connecticut, the products of which declined $275,225 in value during the five years. Pennsylvania reported the largest absolute increase in value of products during this period, $17,956,203, or 41.7 per cent; Illinois reported the next largest gain, $8,910,785, or 53.7 per cent; and Ohio the third largest, $8,453,045, or 65.1 per cent. These were the only states that reported a gain of more than $5,000,000 in value of products in 1905.

In 1900 the order of the states in regard to increase in value of products during the preceding period differed greatly from that shown for 1905. Pennsylvania led as in 1905, but New York and Texas were second and third, respectively, each reporting an increase of more than $5,000,000.

Several of the states reported a decreased production in 1900, but in each case they reported an increase in 1905 over the 1900 returns, the increases of 2, namely, New Jersey and Maryland, being more than $1,000,000.

Tables 11 and 12 present statistics in detail, distributed by states and territories, for each branch of the industry at the census of 1905.

TABLE 11.—CARS, STEAM RAILROAD, NOT INCLUDING OPERATIONS OF RAILROAD COMPANIES—DETAILED SUMMARY, BY STATES: 1905.

STREET RAILROAD CARS AND REPAIRS.

The census of manufactures of 1890 was the first to distinguish between the production of street railroad cars in establishments devoted principally to their construction and the building of cars in the repair shops of street railroad companies incidental to large repair operations which far exceeded in cost the few cars turned out. At the census of 1880 the statistics of the production of street cars and steam railroad cars were merged in one classification, so that no comparative figures prior to 1890 can be given. At the latter census the classification adopted to indicate the two branches of the manufacture of street cars were "cars, street railroad, not including operations of railroad companies," and "cars and general shop construction and repairs by street railroad companies," and they have been retained for this purpose since 1890. These classifications will be denoted, respectively, as "cars, street railroad," and "street railroad repair shops."

In Table 13 the statistics for both branches of the industry are combined, for each census from 1890 to 1905.

The extraordinary growth of the combined industries since 1890 is the logical result of the great development of street railroads which has taken place during the past fifteen years. During the decade between 1890 and 1900 the value of products increased $10,407,717, or 166 per cent, and for the entire period covered by the table the products nearly quadrupled in value. In marked contrast to this increase and to that in all the other items is the comparatively slight increase in the number of establishments from 1890 to 1900 and the decrease in this item which occurred from 1900 to 1905. As will appear from succeeding tables, this decrease characterized the operations of both branches of the industry and was due principally to combinations of street railroads, which has resulted in the construction of central repair shops that have taken the place of many small ones, and to the concentration of car building in large establishments devoted entirely to the construction of street railroad cars.

TABLE 13.—*Cars, street railroad, and street railroad repair shops—comparative summary, with per cent of increase: 1890 to 1905.*

	CENSUS.			PER CENT OF INCREASE.

[1] Decrease.

Of the total of 100 establishments engaged in the combined industry at the census of 1905, 86 were street railroad repair shops. Notwithstanding the fact that there were six times as many repair shops as establishments engaged primarily in the manufacture of street railroad cars, the latter represented an investment of $12,975,703, or 50.1 per cent of the capital employed in the combined industry, and produced a

product valued at $10,844,196, or 44.7 per cent of the value of the combined products of the two branches of the industry. The repair shops, however, employed 11,052 wage-earners and paid in wages $7,012,798, which constituted 70 and 71.2 per cent, respectively, of the total for the combined industries.

Indications of the difference in the nature of the work performed by the two classes of establishments are developed by a comparison of the statistics of the number of wage-earners employed, the cost of materials, and the value of the products resulting from their operations. The repair work of the street railroad repair shops in general consists largely of labor unassisted, or assisted but little, by machinery, operating upon materials often already in position; whereas in the construction of street cars on a large scale labor is augmented by machinery wherever possible, and the comparatively large quantity of new work resulting necessarily involves the expenditure of a larger sum for materials in proportion to the value of the products than is the case with the repair shops. Thus, at the census of 1905 the cost of labor and the cost of materials constituted 26.2 per cent and 49.2 per cent, respectively, of the value of the products produced by the manufacturers of street cars, and 52.2 per cent and 40.6 per cent, respectively, of the value of the products of street railroad repair shops.

Products.—Table 15 shows the number and value of all street cars manufactured, as reported at the census of 1905, distributed according to character of establishments and kind of cars. With respect to this information no effort previous to the present census has been made to obtain complete data, so that no comparative figures are available.

TABLE 15.—*Number, kind, and value of street railroad cars built by all establishments: 1905.*

	Number.	Value.

[1] Includes 288 cars, valued at $580,669, enumerated only as "passenger cars."

At the census of 1905, 4,694 street cars were produced, of which 3,966, or 84.5 per cent, were built in establishments devoted primarily to the construction of street cars. Only 310 cars, or 6.6 per cent of the total number produced, were built in street railroad repair shops, which was 108 cars less than the number constructed in establishments engaged primarily in the production of steam railroad cars.

The value of the cars manufactured during the census year in street car manufacturing establishments and in street railroad repair shops was $8,907,656, which constituted only 36.7 per cent of the aggregate value of the products of the combined industries. Thus the value of the new cars built amounted to about one-third, and the value of the repair work to about two-thirds, of the combined value of products of the two industries which build and keep in repair the rolling stock of street railroads. The value of street cars manufactured in establishments devoted to their construction was $8,302,512, or 76.5 per cent of the value of products of this branch of the combined industries; while in the case of the repair shops the value of the cars produced, $605,144, formed only 4.5 per cent of the total value of products.

The average value per car of all cars built during the census year was $2,110. Of the three classes, as distinguished in the table, of establishments producing street cars, the lowest average value per car resulted from the building operations of the railroad repair shops, and the cars of the greatest average value were constructed by establishments producing primarily steam railroad cars. The low average value of the cars built in street railroad repair shops was caused by the fact that a large number were freight and work cars constructed in many cases of old trucks and other portions of passenger cars which had been condemned for passenger traffic. Moreover, many of the passenger cars reported as built were old passenger cars reconstructed and newly equipped with up to date motors and brakes. It is natural, therefore, that the average value per car should be less than that for the other two classes of establishments shown in the table which produced for the most part new work.

Since 1900 considerable improvement in the rolling stock of street railroads has taken place. In general the size of cars has been increased and they have been made more comfortable and more suitable to the demands of a rapidly increasing traveling public. On the interurban lines, which are usually in direct competition with the steam railroads, it is essential that the comfort of the car should approach as nearly as possible that of the steam railroad coach. It follows that each year more costly cars are being produced by the street car manufacturers. Evidence of the fact can be found in the reports of 3 large establishments that at the census of 1900 reported 1,603 cars built during the census year with an average value of $1,387, while the same 3 companies at the census of 1905 reported the construction of 1,597 cars during the census year with an average value per car of $2,393.

Further evidence of the progressive changes in this respect which have taken place since 1900 is obtainable from a comparison of the number and value of street cars produced during that census year by establishments engaged primarily in the manufacture of steam railroad cars, with the number and value of the cars produced by the same class of establishments at the present census. According to the special report on cars, steam railroad, for 1900, 935 street railroad

cars of an average value of $1,167 were finished during the census year by manufacturers of steam railroad cars, while for 1905 this class of establishments reported the construction of 418 cars with an average value of $2,380.

Table 15 shows that practically all the cars produced were for electrified street railroads. No cable cars were reported and only 42 for horsepower. Over two-thirds of the electric cars turned out were closed cars. The perfection of the combination car, namely, a car which is devoted in part to freight and in part to passenger traffic, is a matter of comparatively recent date, but now they are much used on the interurban lines of the middle West, and during the census year nearly as many cars of this character as open cars were built. The average value of the combination car was $2,493, or $244 more than that of the closed, and $950 more than that of the open cars.

STREET RAILROAD REPAIR SHOPS.

Table 16 is a summary of the statistics of the street railroad repair shops, distributed according to geographic divisions.

TABLE 16.—STREET RAILROAD REPAIR SHOPS—SUMMARY, BY GEOGRAPHIC DIVISIONS: 1905.

DIVISION.	Number of establishments.	Capital.	SALARIED OFFICIALS, CLERKS, ETC.		WAGE-EARNERS AND WAGES.		Miscellaneous expenses.	Cost of materials used.	Value of products.
			Number.	Salaries.	Average number.	Wages.			
United States	86	$12,905,853	499	$542,687	11,052	$7,012,798	$418,276	$5,463,360	$13,437,121
North Atlantic [1]	37	8,017,711	242	248,978	6,372	3,926,403	231,257	2,775,103	7,181,741
South Atlantic [2]	5	278,942	23	21,667	240	119,895	6,782	124,932	273,276
North Central [3]	31	3,921,481	119	151,107	3,077	1,944,808	162,549	1,767,383	4,025,847
South Central [4]	4	117,050	6	6,449	124	63,560	5,438	71,743	147,190
Western [5]	9	570,669	109	114,486	1,239	958,132	12,250	724,199	1,809,067

[1] Includes Maine, Massachusetts, Connecticut, New York, New Jersey, Pennsylvania.
[2] Includes Delaware, District of Columbia, Virginia.
[3] Includes Ohio, Illinois, Michigan, Wisconsin, Minnesota, Iowa, Missouri, Nebraska, Kansas.
[4] Includes Kentucky, Texas.
[5] Includes Colorado, Utah, Washington, Oregon, California.

The number of repair shops in each division is indicative of the development of the street railroad in the different sections of the country. It is natural that the North Atlantic division, embracing states for the most part far more densely settled than those of the other divisions, should exceed them in every statistical item shown in the table. The second division in this respect was the North Central, which had 31 establishments, as compared with 37 in the North Atlantic division; but the latter gave employment to twice as many wage-earners as the former and accomplished construction and repair work valued at nearly twice as many dollars. Thus, while the North Central reported nearly as many establishments as the leading division, yet when measured by the average number of wage-earners employed and the value of product, the operations of the average establishment in the North Atlantic division were nearly twice as extensive as those of the average establishment of the North Central division.

Tables 17 and 18 show statistics in detail for cars, street railroad, not including operations of railroad companies, and cars and general shop construction and repairs by street railroad companies, respectively, distributed according to states, as far as it is possible to show the states separately without disclosing the operations of single establishments.

TABLE 17.—CARS, STREET RAILROAD, NOT INCLUDING OPERATIONS OF RAILROAD COMPANIES—DETAILED SUMMARY, BY STATES: 1905.

	United States.	Ohio.	All other states.[1]
Number of establishments	14	4	10
Capital, total	$12,975,703	$1,748,065	$11,227,638
Land	$972,804	$61,294	$911,510
Buildings	$1,823,271	$297,942	$1,525,329

CHEMICALS AND ALLIED PRODUCTS

CHEMICALS AND ALLIED PRODUCTS.

By CHARLES E. MUNROE, Professor of Chemistry, George Washington University, Expert Special Agent.

SCOPE OF THE CENSUS.

The first special report on the manufacture of chemicals was made at the census of 1880 under the caption "chemical production." At each subsequent census a special report on this topic has been made under the caption "chemicals and allied products." Inspection of these reports shows that the industries included have varied considerably, though each report has embraced the industries producing acids, sodas, potashes, alums, glycerin, dyestuffs and extracts, explosives, fertilizers, pigments, wood distillation products, salts, and certain elementary substances, such as bromine and phosphorus. The special report at the census of 1880 also embraced the industries producing soap, candles, castor oil, glucose, and sulphur, the products of which had a total value of $28,010,152. These latter industries did not appear in the special report of 1890, but those producing pharmaceutical preparations, ready mixed paints, and varnishes and japans were added, the pharmaceutical preparations having a value of $16,744,643. All the industries embraced in the special report for 1890 were included in the special report for 1900 and in the present report, with the exception of pharmaceutical preparations, while those producing essential oils and bone, ivory, and lamp black were added, these latter industries reporting in 1900 products valued at $1,173,282, and in 1905 products valued at $2,112,379. The manufactures included under any industry may, however, differ somewhat from census to census as new products of the same general character are put upon the market or older ones cease to be used. The returns in the establishments enumerated were classified according to that class of product which had the maximum value, as is the rule in all Census classification, but many of these establishments produced also subsidiary products of less value, which, had they been returned as principal products, would have placed these establishments in other classes. Such subsidiary products appear in the tabular summaries of the Census reports under the heading "all other products," but in some cases they are also treated of in the text and in the minor tables of their special classes.

A reason for the variation in the industries included at the different censuses is found in the very general and indefinite title used, for in the strictest technical sense every material thing is a chemical, and accordingly every industry in which the materials used undergo a chemical change in the process of manufacture, as in the smelting of iron from its ores or the production of leather from a hide, may be considered as a chemical industry. It is evident that if this view of the significance of the title were taken, "chemicals and allied products" would properly cover every manufacture except those like furniture making, machine construction, or textiles, in which the material remains unchanged in composition during the manufacture but is turned, or cast, or woven into other shapes. The popular idea of the term limits its application but admits as chemical industries the manufacture of gunpowder, fertilizers, and similar mixtures, whose ingredients undergo no chemical change during the process of compounding the mixtures. It thus becomes necessary to decide arbitrarily upon the industries to be included. Those so included at the census of 1905 may be divided into the following classes:

I. A. Sulphuric, nitric, and mixed acids.
I. B. Other acids.
II. Sodas.
III. Potashes.
IV. Alums.
V. Coal tar products.
VI. Cyanides.
VII. Wood distillation.
VIII. Fertilizers.
IX. Bleaching materials.
X. Chemicals produced by the aid of electricity.
XI. Dyestuffs.
XII. Tanning materials.
XIII. Paints and varnishes.
XIV. Explosives.
XV. Plastics.
XVI. Essential oils.
XVII. Compressed and liquefied gases.
XVIII. Fine chemicals.
XIX. General chemicals.

This classification is precisely that followed at the census of 1900, except that Class I is at the present census subdivided into Subclasses A and B, and pre-

cisely the same industries are included in each case. From the list given it is apparent that "chemicals and allied products" includes twenty distinct industries. As a matter of fact, the number is very much greater. This becomes evident when it is recalled that nitric acid differs from sulphuric acid as greatly as paper from leather, and that the processes used in the manufacture of the two acids differ as much as do those used in making paper and leather.

TABLE 1.—*Chemicals and allied products—comparative summary, with amount and per cent of increase: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Number of establishments	1,786	1,691	95	5.6
Capital	$323,997,131	$238,471,290	$85,525,841	35.9
Salaried officials, clerks, etc., number	11,147	8,602	2,545	29.6
Salaries	$15,014,018	$11,339,595	$3,674,423	32.4
Wage-earners, average number	59,198	46,700	12,498	26.8
Total wages	$29,515,863	$21,783,335	$7,732,528	35.5
Men 16 years and over	56,678	44,574	12,104	27.2
Wages	$28,834,403	$21,198,520	$7,635,883	36.0
Women 16 years and over	2,362	1,949	413	21.2
Wages	$649,296	$554,128	$95.168	17.2
Children under 16 years	158	177	[1] 19	[1] 10.7
Wages	$32,164	$30,687	$1,477	4.6
Miscellaneous expenses	$26,258,768	$14,822,853	$11,435,915	77.2
Cost of materials used	$176,400,690	$124,018,044	$52,382,636	42.2
Value of products	$282,169,216	$202,506,076	$79,663,140	39.3

[1] Decrease.

Because of the variation in the industries included at the successive censuses, only a partial comparison of the data can be made, except for the censuses of 1900 and 1905, when the industries included were identical. The general statistics for the establishments actively engaged in the manufacture of chemicals and allied products in 1900 and 1905, together with the amount and per cent of increase in each item for this period, are set forth in Table 1.

The term "capital" as used in the Census reports refers only to the sum invested in lands, buildings, machinery, and tools and implements, and the funds required to carry on the business, and does not include capital stock.

Table 1 shows an increase for 1905 over 1900 in every item except the number of children employed. It is particularly to be noted that though the number of children employed was reduced by 19, the wages paid them increased by $1,477. The data given in this table indicate a most flourishing condition for the industry as a whole. A clearer idea would be gained of the economic conditions that existed if a separate presentation were made of each industry included in this class. This is not feasible at this point, but the data may, as in 1900, be divided for comparison among six subclasses which are popularly regarded as separate industries. Table 2 presents a comparative summary of these subclasses.

TABLE 2.—COMPARATIVE SUMMARY, BY INDUSTRIES: 1905 AND 1900.

	CHEMICALS.[1]		DYESTUFFS AND EXTRACTS.		ESSENTIAL OILS.		EXPLOSIVES.		FERTILIZERS.		PAINTS AND VARNISHES.[2]

Wages	$16,999	$11,652	$580	$661	.....	.....	$100	$6,088	$3,469	$2,973	$11,016	$9,313
Miscellaneous expenses	$8,937,242	$4,362,608	$944,360	$458,212	$78,886	$48,763	$1,657,665	$1,096,604	$4,919,824	$3,734,285	$9,720,791	$5,122,381
Cost of materials used	$51,883,219	$34,545,862	$6,829,340	$4,745,912	$1,110,470	$588,594	$17,203,667	$10,334,974	$39,343,914	$28,958,473	$60,030,070	$44,844,229
Value of products	$92,088,378	$62,637,008	$10,883,113	$7,350,748	$1,464,662	$813,495	$29,602,884	$17,125,418	$56,632,853	$44,657,385	$91,487,326	$69,922,022

[1] Includes sulphuric, nitric, and mixed acids, and wood distillation.

[2] Includes bone, ivory, and lamp black.

At each census chemicals ranked first in capital, number of wage-earners employed, and total wages paid, being followed at each census by paints and varnishes, fertilizers, explosives, dyestuffs and extracts, and essential oils in the order named. At each census paints and varnishes ranked first in number of salaried officials, clerks, etc., salaries, miscellaneous expenses, and cost of materials used, with chemicals second, and the other industries in the order given above. Paints and varnishes ranked first in value of products, and chemicals second at the census of 1900, but this order was reversed at the census of 1905.

[1] Decrease.

[2] None reported in 1905.

In but one industry—chemicals—was there an increase in every item. The number of establishments increased in every industry except fertilizers, which showed a loss of 22. In each of the six industries there was a gain in capital, wages, miscellaneous expenses, cost of materials, and value of products. In two industries, fertilizers and essential oils, the number of salaried officials, clerks, etc., decreased, though the amount paid in salaries declined only in the former. The absolute increases were greatest in chemicals for every item except number of establishments, numbers of women and children wage-earners, wages paid to women, and miscellaneous expenses, but the percentages of increase fluctuated markedly, explosives showing the greatest percentage of increase in number of establishments, capital, salaried officials, and salaries; dyestuffs and extracts the greatest for wage-earners, wages, and miscellaneous expenses; and essential oils the greatest for cost of materials and value of products.

Marked fluctuations are shown in the number of establishments in the different states and territories, the largest increase, 29 establishments, occurring in Georgia, and the greatest decrease, 21 establishments, in New York. Increases occurred in 25 states and territories, and decreases in 17 states and territories. Three states and territories, Alaska, Indian Territory, and Wyoming, appear for the first time at this census, while Arizona, which reported 1 establishment in 1900, did not return any in 1905. Considered by geographic divisions, the North Atlantic suffered a decrease of 26 establishments, the South Atlantic gained 59, the North Central 25, the South Central 21, and the Western 16 establishments. In 1900 establishments were reported from 40 different states and territories, and in 1905 from 42, there being at the latter census 8 states and territories, namely, 2 in the North Central, 2 in the South Central, and 4 in the Western division, from which no returns for establishments were received.

[1] Decrease.

Notwithstanding considerable decreases in 3 of these states, Pennsylvania, New York, New Jersey, and Ohio occupied the first four places in rank, in the order named, at the census of 1905 as well as at that of 1900. Illinois occupied fifth place at both censuses, and Massachusetts sixth. Georgia advanced from eleventh to seventh place, and California from tenth to

eighth, while Virginia fell from seventh to ninth, Maryland from eighth to tenth, and Michigan from ninth to eleventh, a rank shared at this census with Indiana. The greatest advance in rank was made by West Virginia, which passed from twenty-fourth place in 1900 to seventeenth in 1905. The largest decline in rank was that of the District of Columbia, which dropped from twenty-fifth to thirtieth place.

TABLE 5.—QUANTITY AND COST OF MATERIALS USED, WITH AMOUNT AND PER CENT OF INCREASE, AND AVERAGE COST PER UNIT: 1905 AND 1900.

	CENSUS.		Increase.	Per cent of increase.	COST PER UNIT.	
	1905	1900			1905	1900

Cost	$1,674,031	$1,724,857	[1] $50,826	[1] 3.0	$21.78	$20.65
Tallow and fat	$238,881	$380,517	[1] $141,636	[1] 37.2		
Wood ashes—						
Bushels	210,083	801,047	[1] 590,964	[1] 73.8		
Cost	$26,175	$39,507	[1] $13,332	[1] 33.8	$0.12	$0.05
All other components of products	$32,381,443	$24,497,258	$7,884,185	32.2		
Fuel	$7,560,710	$5,515,636	$2,045,074	37.1		
Mill supplies	$760,642	$779,814	[1] $19,172	[1] 2.5		
All other materials	$37,154,806	$13,066,053	$24,088,753	184.4		
Rent of power and heat	$773,672	$297,568	$476,104	160.0		
Freight	$1,525,726	$3,143,972	[1] $1,618,246	[1] 51.5		

[1] Decrease.

Unless otherwise specified, the ton mentioned in text and tables is the short ton of 2,000 pounds.

It appears that in 1905 as compared with 1900 there was an increase in the quantity of each of the

materials reported as used in every case except for limestone, lime, nitrate of potash, sulphur, and wood ashes. For the cost of materials used, increases were reported in every item except bones, tankage, and offal, nitrate of potash, sulphur, tallow and fat, wood ashes, mill supplies, and freight, in which there was reported a decrease in total cost. The decrease in quantity and cost of nitrate of potash is more than offset by the increase in quantity and cost of nitrate of soda, which is a substitute for the former for the majority of uses and is much cheaper. The decrease in quantity and cost for sulphur is more than offset by the increase in quantity and cost of pyrites, which, as later shown, is a most satisfactory substitute for sulphur in the sulphuric acid industry. The decrease in quantity and cost of wood ashes, which are used as a source of potassium compounds, is more than offset by the increase in potash salts. Part of the decrease in wood ashes is, however, to be accounted for by the difference in the method of taking the census of 1905 from that of 1900, as this industry is largely a neighborhood industry. The decrease in bones, tankage, and offal, which are used as sources of nitrogen, phosphorus, and potassium in the compounding of fertilizers, is more than offset by the increases in fish, ammonium sulphate, cottonseed meal, and nitrate of soda, all of which supply nitrogen; in fish, phosphate rock, and acid phosphate, which supply phosphorus; and in potash salts, which supply potassium. The other decreases are not as well accounted for, but it is probable that the decreases in mill supplies and freight are to some extent offset by the increase of 264.2 per cent in "all other materials," while the cost of freight may also have been included in the cost returned for the various materials to a larger extent in 1905 than in 1900. No obvious explanation is at hand to account for the decrease in limestone and lime, but that in tallow and fat probably arose from the fact that soap, candles, etc., for which these materials are chiefly used, have become the product of maximum value in certain establishments, so as to carry them out of the classification of chemicals and allied products, under which they were included in 1900, and into another class.

The average cost per unit of quantity shows an increase for every item presented except phosphate rock, wood for extracts, aqua ammonia, ammonium sulphate, grain alcohol, wood alcohol, common salt, and linseed oil. It is surprising that there have not been more instances of decrease when it is considered that these averages take no account of grades and that there are wide variations in the quantities and values of the different grades of many of these articles. This is emphasized in the detailed study of sulphuric acid, given further on, when four different commercial grades, ranging in value from $7.11 to $27.20 per ton, are shown. It is probable that the decrease in the cost of wood for extracts was due to an increased use of a lower grade of wood. The decrease in the cost of aqua ammonia and ammonium sulphate is in entire harmony with the statistics set forth in Census Bulletin 65, on Coke, and results from the extension of the by-product coke industry and the greatly increased production, through this means, of ammonia liquor and ammonium sulphate. The decrease in the cost of wood alcohol follows a similar extension of the wood distillation industry, which is another by-product industry; while that in the cost of grain alcohol is due to the greatly increased use of tax-free alcohol in the manufacture of smokeless powder for the United States Government.

TABLE 6.—*Quantity and value of products, with amount and per cent of increase: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.

[1] Decrease.

The increase of $79,663,140 in the aggregate value of products indicates that the condition of the industries grouped under chemicals and allied products was, on the whole, most prosperous in the census year 1905. Nevertheless, in the case of 18 of the products enumerated in Table 6, a decrease was reported either in quantity or in value, or both, at the census of 1905 as compared with that of 1900. In some cases these decreases were not actual, but merely due to the manner of tabulation; as in many instances establishments classified under this heading in 1900 have been transferred in 1905 to other classifications because of a change in their principal product. The coal tar products may be cited as an example. Through the growth of the manufacture of tarred paper and other materials of this class the value of these materials has come, in several establishments, to exceed that of the coal tar distillery products and the chemicals made from them

in these same establishments, and thus establishments which at the census of 1900 were classified as engaged in the manufacture of coal tar products were, at the census of 1905, classified as engaged in the manufacture of roofing and roofing materials. In such instances it is endeavored, when possible, to obtain from the returns of these establishments the quantity and value of the subsidiary coal tar products reported, and to combine these figures with those from the establishments in which coal tar products were the principal products, so as to give as complete a view as possible of the special industry. The results of this method as applied to this and other industries are set forth further on, where the different subindustries are treated in detail.

The decreases in some items shown in Table 6 may be ascribed to an increase in the practice of using within an establishment products of its manufacture in the manufacture of other products. Thus the decrease in the quantity and value of natural tanning materials, ground or chipped, is more than offset by the increase in the quantity and value of the extracts, which indicates that establishments which formerly sold their natural tanning material in the ground or chipped condition are now using much of it in the preparation of tanning extracts, and thereby securing the additional profit and advantage which results from further manufacture. The reduction in the quantity and value of dry white lead, as produced for sale, may also be due partly to establishments engaged in the corrosion of lead extending their operations to grinding this white lead in oil before offering it for sale, and thereby converting the pigment into a paint. Cases which arise, such as the two mentioned, will also be considered in the detailed discussion of the subclasses.

TABLE 7.—*Products consumed in establishments where manufactured, with amount and per cent of increase: 1905 and 1900.*

KIND.	CENSUS.		Increase.	Per cent of increase.
	1905	1900

Nitroglycerin, pounds	44,077,828	31,661,806	12,416,022	39.2
Pyroxylin, pounds	2,938,266	1,964,345	973,921	49.6
White lead, dry, tons	77,793	65,811	11,982	18.2
All other products consumed, tons	2,561,666	272,560	2,289,106	839.9

Table 7 shows that at the census of 1905, as compared with that of 1900, there was an increased consumption of products in the establishments in which they were manufactured, in the case of every substance mentioned in the table. The amount of increase was greatest in the case of sulphuric acid and least in the case of pyroxylin. The percentage of increase was greatest in the case of nitrate of ammonia and least in the case of acid phosphate. The increases recorded were undoubtedly all due to active business conditions and an improved demand for these products, except perhaps in the case of charcoal. In this instance certain establishments making charcoal for use in blast furnaces by wood distillation methods were, at the present census, by the operation of the Census rule for classification, transferred to the group "chemicals and allied products" from the group "iron and steel and their products" or the group "lumber and its remanufactures," where they were placed at the census of 1900.

The figures of Table 7 are of special interest when considered in connection with those of Table 6. Thus, for instance, the returns for lead oxides and white lead, dry, given in Table 7, confirm the opinion that the decreases shown for these products in Table 6 were due largely to their increased consumption in further manufacture in the establishments where they were originally manufactured.

CLASS I. A.—SULPHURIC, NITRIC, AND MIXED ACIDS.

Sulphuric acid, which has been known to man since the eighth century, and which has been manufactured on a commercial scale in the United States since 1793, is so extensively used in the manufacture of other chemical products that the statistics for its production have been regarded as a safe criterion by which to gauge the activity of a country in chemical manufactures. Nitric acid was manufactured in this country as early as 1834. Mixed acids, which are mixtures of sulphuric and nitric acids in various proportions, came into commercial use about 1860, and the consumption of them for the manufacture of nitroglycerin, gun cotton, picric acid, and a large number of organic nitrates and nitro-substitution bodies has grown rapidly.

The classification "sulphuric, nitric, and mixed acids" is adopted for the first time at the present census, the industry having now attained such magnitude and significance as to warrant it. The statistics for sulphuric acid have been collected separately at each census, beginning with the census of 1870, and at the censuses of 1890, 1900, and 1905 the quantities and values of each of the important commercial grades of the acid were also ascertained. The statistics for nitric and mixed acids were first collected separately at the census of 1900. The statistics for the three acids named were presented in the special report on chemicals and allied products for 1900 in conjunction with those for muriatic, boric, acetic, lactic, citric, tartaric, and other acids, under the heading "acids." The returns for 1900 were, however, so recorded that it has been possible to separate accurately the returns for sulphuric, nitric, and mixed acids from those for the other acids reported, so that a comparison of the statistics for these three acids for the last two censuses may be made. These statistics are sum-

marized in Table 8, which gives only the statistics of establishments engaged primarily in the manufacture of the products in question.

[1] Decrease.

Although the total number of establishments primarily engaged in the manufacture of sulphuric, nitric, and mixed acids, the capital employed, the quantities of sulphur and nitrate of soda used, and the value of "all other products" were less at the census of 1905 than at that of 1900, a healthy growth is indicated by the fact that there was an increase in all the other items. The relative increase in yields especially indicates improvement in operation.

The products included in Table 8 are those only which are produced for sale, and by establishments in which they constitute the principal product. A better idea of the industry may be gained by combining with the figures given those for the acid produced by establishments in which it constitutes a subsidiary product, and also those for acid which is produced and consumed in the same establishment in further manufacture, giving to this "consumed" acid the average value per unit of its grade so as to obtain a total value for the product. Among establishments of this kind may be mentioned chemical works in which various other acids, bases, salts, or other compounds are produced having a value greater than the sulphuric, nitric, or mixed acids produced for sale, or which consumed one or more of these acids in further manufacture; fertilizer works where sulphuric acid is extensively produced and used in making superphosphates; explosive factories where the sulphuric and nitric acids produced are converted into mixed acids and consumed in the manufacture of nitroglycerin or gun cotton and other cellulose nitrates; petroleum refineries where the sulphuric acid produced is consumed in refining oil; and smelting works where sulphuric acid is obtained from the sulphur fumes. This method has been adopted in treating of sulphuric acid so that comparisons may be made showing the growth in the production at the different censuses.

Sulphuric acid.—The census of 1870 was the first at which separate statistics were given for sulphuric acid, and then only for the number of establishments and the total value of the product. From evidence since obtained it is believed that these statistics are deficient, and that at that time there were probably 25 establishments in operation, yielding a product of over $1,000,000 in value. At the census of 1880 the total quantity of sulphuric acid was also reported, as well as its value and the number of establishments producing it.

TABLE 9.—*Sulphuric acid—number of establishments and quantity and value of products: 1870 to 1905.*

1870 to 1880	[1]	3,449,726	[1]	1,626.1

[1] Not reported.

Sulphuric acid is produced in several grades: (1) 50° Baumé, or chamber acid, containing on an average 51.04 per cent of SO_3; (2) 60° Baumé, containing on an average 63.7 per cent of SO_3; (3) 66° Baumé, known as oil of vitriol, containing on an average 76.35 per cent of SO_3; and (4) oleum, which consists of SO_3 dissolved in a sulphuric acid, containing 97 to 98 per cent of H_2SO_4. Pure pyrosulphuric acid contains 89.89 per cent of SO_3. The commercial article, called "oleum," usually contains 30 per cent of free SO_3, or a total of 87.14 per cent of free and combined SO_3. Beginning with the census of 1890 the statistics for the separate grades have been collected, and it thus becomes possible to show more definitely the condition of the industry at the different censuses, although the sum

total of all the grades gives but an incomplete statistical view of the industry. It is also possible to reduce all the grades to a common basis, as, for instance, to the basis of 50° Baumé, or chamber acid. For this purpose the quantity given for 60° Baumé is multiplied by the factor 1.25; that given for 66° Baumé, by the factor 1.50; and that given for oleum, by the factor 1.71.

TABLE 11.—TOTAL QUANTITY AND VALUE OF SULPHURIC ACID, BY GRADES: 1890 TO 1905.

GRADE.	1905			1900			1890		
	Quantity (tons).	Value.	Value per ton.	Quantity (tons).	Value.	Value per ton.	Quantity (tons).	Value.	Value per ton.
Total reduced to 50° Baumé acid	[1] 1,869,437			[2] 1,548,123		$9.20	[3] 783,569		
Total	1,642,262	$15,174,886		1,352,730	$14,247,185		692,389	$7,679,473	
50° Baumé	1,169,141	8,314,646	$7.11	953,439	7,965,832	8.35	504,932	4,307,067	$8.53
60° Baumé	48,688	581,523	11.94	17,012	246,284	14.47	10,190	122,940	12.06
66° Baumé	411,165	5,917,699	14.39	382,279	6,035,069	15.78	177,267	3,249,466	18.33
Oleum	13,268	361,018	27.20						

[1] Includes 968,445 tons, with an assigned value of $7,232,675, consumed in establishments where manufactured; and also sulphuric acid produced by establishments engaged primarily in the manufacture of other products.
[2] Includes 764,355 tons, with an assigned value of $7,032,066, consumed in establishments where manufactured; and also sulphuric acid produced by establishments engaged primarily in the manufacture of other products.
[3] Includes 290,768 tons, for which no value was assigned, consumed in establishments where manufactured; and also sulphuric acid produced by establishments engaged primarily in the manufacture of other products.

Comparing the total quantities reduced to the common basis of 50° Baumé, it appears that the increase for 1900 over 1890 was 764,554 tons; and for 1905 over 1900, 321,314 tons. The per cent of increase for 1900 over 1890 was 97.6; and for 1905 over 1900, 20.8. The value per ton for each grade has been consistently lower at each census except for the 60° Baumé. For this grade a higher value was reported at the census of 1900 than at that of 1890, but the value reported at the census of 1905 is less than that for 1890, and is in harmony with the values reported for the other grades at the present census. This progressive reduction in the cost of sulphuric acid is a matter of prime importance, since this acid is used to so large an extent in the manufacture of other products.

Oleum appears for the first time in any census at the census of 1905. This is due to the fact that it is readily produced by the contact process, which was described in detail in the 1900 report on chemicals and allied products, and which had then but recently been made commercially operative and introduced into this country.

The geographic distribution of the manufacture of sulphuric acid is shown in Table 12, which includes all establishments, making it either as a principal or as a subsidiary product, reported at the censuses of 1900 and 1905.

Establishments manufacturing sulphuric acid were reported from 25 states at the census of 1900, and 26 at that of 1905. At the census of 1900 New Jersey held first rank in the number of establishments, Georgia second, Maryland and South Carolina third, and New York and Pennsylvania fourth. Each of the remaining states reported less than 10 establishments in operation. At the census of 1905 Georgia held first rank, and was followed by Pennsylvania, New Jersey, South Carolina, and New York, in the order named.

TABLE 12.—*Sulphuric acid—number of establishments, by states and territories: 1905 and 1900.*

STATE OR TERRITORY.	1905	1900
United States	[1] 149	[2] 127

Texas	1	.....
Virginia	7	5
Wisconsin	1	.....

[1] Includes 117 establishments engaged primarily in the manufacture of other products.
[2] Includes 93 establishments engaged primarily in the manufacture of other products.

None of the remaining states reported 10 establishments in operation. Maine and Missouri each reported 1 establishment in operation at the census of 1900, but none at the census of 1905, while Kansas, which reported 3 establishments, and Texas and Wisconsin, which reported 1 establishment each at the census of 1905 did not report any at the census of 1900. At the census of 1900, out of the total number of establishments reported, 95, or 74.8 per cent, were located in states bordering on the Atlantic ocean or the Gulf of Mexico, and at the census of 1905, of the establishments reported, 97, or 65.1 per cent, were so located.

TABLE 13.—*Sulphuric acid—quantity of products, by geographic divisions: 1905 and 1900.*

DIVISION.	1905	1900
	Tons.	*Tons.*
United States	1,869,437	1,548,123
North Atlantic	768,647	734,669
South Atlantic	540,593	520,575
North Central	349,906	153,979
South Central	141,107	87,665
Western	69,184	51,235

An increase is shown in each of the divisions, the largest increase, 195,927 tons, having occurred in the North Central division, and the smallest, 17,949 tons, in the Western; while the greatest percentage of increase was that for the North Central.

The census of 1900 was the first at which statistics were given with any detail as to the kinds, quantities, and values of the principal materials. At that census there were reported, as having been used in the manufacture of sulphuric acid, 633,837 tons of pyrites, having a value of $3,101,075, and 70,288 tons of sulphur, having a value of $1,396,975.

At the census of 1905 there were reported 707,326 tons of pyrites, having a value of $3,895,905, and 47,861 tons of sulphur, having a value of $1,022,644. This represents an increase in pyrites, for 1905 as compared with 1900, of 73,489 tons, or 11.6 per cent, in quantity and $794,830, or 25.6 per cent, in value, and a decrease in sulphur of 22,427 tons, or 31.9 per cent, in quantity and $374,331, or 26.8 per cent, in value.

The quantity of nitrate of soda used in the manufacture of sulphuric acid can not be directly ascertained, for the reason that in establishments producing sulphuric acid it is used for other purposes also, varying with the nature of the establishment, as, for example, in making nitric acid, fertilizers, gunpowder, dynamite, or saltpeter; and for the further reason that the nitrate used for all purposes in a single establishment is reported in gross. Analysis of returns, however, shows that on the average 1 part of nitrate is used to every 100 parts of 50° Baumé acid produced. Bearing in mind that no nitrate is used in the contact processes, it is estimated that in 1900 there was used in making sulphuric acid 15,481 tons of nitrate of soda, and in 1905, 18,467 tons. The ratio of nitrate to total acid will probably decrease greatly in the future.

In the report on sulphuric acid for the census of 1880 it was stated that there were then 3 establishments in the United States burning pyrites, from which it is inferred that the other 46 were burning brimstone, as sulphur is usually styled in this industry. In the census report for 1890 no mention is made of the kind of materials used. At the census of 1900 there were 77 establishments burning pyrites only, 31 burning brimstone only, 17 burning both pyrites and brimstone, and 2 producing the acid from the roaster gases in zinc smelting. At the census of 1905 there were 114 establishments burning pyrites only, 19 burning brimstone only, 10 burning both pyrites and brimstone, 5 producing acid from the roaster gases in zinc smelting, 1 producing acid from the roaster gases in copper smelting, and 5 engaged in the recovery from spent or sludge acid. Two of the pyrite plants were also engaged in the recovery of spent acids.

The total amount of recovered acid included in the product for 1905 was approximately 73,346 tons. It is probable that the amount of sulphuric acid recovered, or regained, during the census year was much greater than this, for in many establishments, such as explosives factories, it has been the practice to recover and reuse the acid again and again, and the acid so recovered is not reported. This practice is, however, now being supplanted by that of rebuilding the spent acid with oleum. At the census of 1900 the quantity of acid reported as produced in zinc smelting was 58,828 tons, having a value of $424,670; and at the census of 1905 the quantity so reported was 94,032 tons, having a value of $576,060. This represents a gain for 1905 over 1900 of 35,204 tons, or 59.8 per cent, in quantity and of $151,390, or 35.6 per cent, in value.

The increase between 1900 and 1905 in the number of establishments burning pyrites was 30, or 31.9 per cent; while for those burning pyrites only it was 37, or 48.1 per cent. The decrease for the same period in the number of establishments burning brimstone was 19, or 39.6 per cent; while for those burning brimstone alone it was 12, or 38.7 per cent.

At the census of 1905 the average yield for 105 establishments burning pyrites only was 211 pounds of sulphuric acid, reduced to 50° Baumé, for 100 pounds of pyrites. At the census of 1900 the average for the 39 works for which data are available was 206 pounds of acid for 100 of pyrites. The theoretical yield of chamber acid is given later. In practice 240 pounds have been obtained. At the census of 1905 the average yield for 15 establishments burning brimstone only was 432 pounds of sulphuric acid, reduced to 50° Baumé, for 100 pounds of brimstone. At the census of 1900 the average for the 20 works for which data are available was 402 pounds of acid for 100 pounds of brimstone. The theoretical yield of chamber acid is given later. In practice 446 pounds have been obtained. In the report on this industry for 1900 attention was called to the large use of sulphur in the United States, while practically no brimstone acid was being made in England or on the continent of Europe. The statistics for the present census indicate that our manufacturers are coming into conformity with European practice.

The large use made of pyrites and of sulphur in the sulphuric acid industry and the continued growth of

this industry make it proper to inquire into the extent to which these raw materials are available.

TABLE 14.—*Pyrites produced in, and imported into, the United States: 1895 to 1904.*[1]

[1] United States Geological Survey, "Mineral Resources of the United States, 1904."
[2] Iron pyrites containing 25 per cent or more of sulphur and not more than 3.5 per cent of copper.
[3] Includes production of natural sulphur.

The chief sources of the supply of pyrites imported into the United States are the celebrated Rio Tinto and Tharsis mines of the Huelva district in Spain; the San Domingo mine at Pomaron, Portugal; and the Tilt Cove mines of Pilleys Island, Newfoundland. The residue from the roasting or burning of pyrites is known as pyrites cinders. Sometimes the pyrites contain gold, silver, or other valuable metals in sufficient quantity to warrant treatment to recover these values, and as the sulphur present renders such ores refractory, it is the practice in some instances to send them to sulphuric acid works to be burnt, the cinders then being returned. Under such circumstances no cost is assigned to the pyrites by the sulphuric acid works. Pyrites cinders is useful in smelting acid ores, as the contact mass in certain processes of making sulphuric acid, and in the manufacture of pigment and of copperas; it is also sometimes used as an iron ore in the blast furnace for making pig iron. In 1900 there were returned 62,701 tons of pyrites cinders, having a value of $105,631, and in 1905, 163,276 tons, having a value of $200,940. It is evident that but a small portion of the actual product is utilized.

Pure pyrite contains 53.3 per cent of sulphur. The pyrites commonly used for making sulphuric acid contain from 43 to 48 per cent. When the ore contains over 35 per cent of sulphur it can be ignited and, with a proper supply of air combustion, will continue until the greater part of the sulphur contents are burned, for there is sufficient heat generated by the process to maintain it. Such is not the case when the amount of sulphur in the ore is less than 35 per cent, and additional fuel is required with these low-grade ores.

The statistics for sulphur produced in this country from 1901 to 1904 are combined with those for pyrites, because the sulphur is largely the product of a single mine, and it is desired to avoid showing individual operations. The remainder of the sulphur used for all purposes is imported.

[1] United States Geological Survey "Mineral Resources of the United States, 1904."
[2] Includes lac sulphur and other grades not otherwise provided for, but not pyrite.

It has been estimated that if the rate of increase in the consumption of pyrites and sulphur which obtained between 1893 and 1903 be maintained the amount of sulphur required in the United States in 1913 in the form of elemental sulphur or of sulphur bearing materials would amount to 1,045,875 long tons. As similar activity in manufacture is noted in several European countries, there is already a call for new sources of supply of raw materials. Fortunately there are many sulphur bearing materials, some of which are used as sources of the metals.

Table 16 presents the names of several of the more commonly occurring sulphur bearing minerals, with their formulas, and the number of tons of "real" sulphuric acid and of chamber acid which theoretically may be produced from a ton of each mineral when pure.

TABLE 16.—*Tons of real sulphuric acid and of chamber acid theoretically produced by a ton of each of the minerals specified.*

MINERAL.	Formula.	Real sulphuric acid.	Chamber acid.
Sulphur	S	3.06	4.93
Pyrite	FeS_2	1.63	2.62
Marcasite	FeS_2	1.63	2.62
Pyrrhotite	$Fe_{11}S_{12}$	1.18	1.90
Sphalerite	ZnS	1.01	1.63
Chalcopyrite	$CuFeS_2$	1.08	1.73
Bornite	Cu_3FeS_3	0.86	1.38
Chalcocite	Cu_2S	0.62	1.00
Galenite	PbS	0.41	0.66

Of the minerals named, sulphur, pyrite, and marcasite have long been used for making sulphuric acid. In the report for 1900 the use of sulphur for this purpose was traced back to Basilius Valentinus, living in the fifteenth century. The first proposal to use pyrites for this purpose is credited to an Englishman named Hill,[1] a patent for the process having been granted him in 1818. Little use was made of it until 1838, when the Sicilian government sold the monopoly of the export sulphur to a French firm, and the price of

[1] George Lunge, Manufacture of Sulphuric Acid and Alkali, edition 1903, Vol. I, pages 36 to 38.

crude brimstone was nearly trebled. Pyrites were found so satisfactory a substitute that they have steadily grown in favor ever since.

Pyrrhotite has come into use practically since the last census. Its value was demonstrated at Sault Ste. Marie, with Canadian ores, and the results were so satisfactory that works have been erected in which to utilize the pyrrhotite ores of Virginia. Pyrite, marcasite, and pyrrhotite, in the condition in which they occur as ores, are all embraced in pyrites.

Sphalerite is used as a source of zinc, and at each of the last two censuses sulphuric acid has been reported as having been produced in the process of zinc smelting. Pure zinc sulphide contains 32.9 per cent of sulphur, but the ores may range down to 18 per cent. In roasting these lower grade ores fuel is required in addition to that furnished by their sulphur contents. When this was added directly, as in earlier practice, the roaster gases were so dilute as to make the recovery of the sulphur difficult, but by roasting in muffles in such a manner as to keep the roaster gases separate from the fire gases, it has become possible to utilize the whole of the sulphur contents of the ore in vitriol chambers, and with the introduction of the contact process, it has even become feasible to recover it from the more highly diluted gases. As early as 1855 there was erected at Stolberg, Germany, a Hasenclever furnace by which the roaster gases from sphalerite, or zinc blende, could be converted into sulphuric acid.

Chalcopyrite, bornite, and chalcocite are copper ores. In 1905 a small amount of sulphuric acid was reported as having been produced in the process of copper smelting. The burner gases from copper smelting are quite lean in sulphur, yet as long ago as 1872 they were used at Altenau, Germany, in making sulphuric acid. By the use of a contact process their utilization becomes still more feasible. The Census report on mines and quarries for 1902 states that 11,780,064 tons of copper ores were mined in that census year, and it is well known that a large percentage of them were sulphur bearing ores.

No reports of sulphuric acid production have been received from any processes of smelting lead ores. Referring to galenite, Lunge says:[1] "Galena is probably nowhere worked in such a way as to extract its sulphur in the shape of sulphuric acid. The purest galena contains only 13.4 per cent of sulphur." The Census report on mines and quarries for 1902 states that 132,330 tons of nonargentiferous lead ore were mined in that census year. The greater part of this was sulphide ore. In addition, 9,787,804 tons of gold and silver ores were reported as being treated in that census year, much of which consisted of sulphurets, the sulphur from all of which was evidently lost in treatment. By Salom's process of electrolyzing galenite, however, hydrogen sulphide is obtained, and this may be converted into sulphuric acid.

According to W. D. Harkins,[2] the amount of material of industrial value given out in smelter smoke in the United States is often enormous. The analysis of the smoke of one smelter showed an approximate daily output in smoke of 55,000 pounds of arsenic trioxide, 1,500 to 2,000 tons of sulphur dioxide, 150 tons of sulphur trioxide, 6,000 pounds of zinc, 5,000 pounds of copper, 6,000 pounds of lead, and 5,000 pounds of antimony. From private communications it is learned that 1 establishment is daily liberating into the atmosphere 850 tons of sulphur in various states of combination, and that another, in a widely different section of the country, is sending off in its smoke approximately 237,500 tons of sulphur dioxide per annum. It has been estimated[3] that a half million tons of sulphuric acid could be produced annually from the sulphur in the fuel burned in London.

This sulphur is not only wasted, but the emanations from smelters render the atmosphere noxious to man and other animals, and seriously affect the vegetation for considerable distances about the smelters. This has repeatedly led to litigation. So long ago as 1864 the owners of the works at Freiberg, Germany, were compelled to pay upward of $14,000 damages on account of the emanations from their works. The recovery and utilization of these gases and fumes will not only abate the evils to which they give rise, but will greatly increase the available supply of the sulphur compounds and other substances which are much used in our industries.

The Tennessee Copper Company has recently erected a plant for making acid from the gases of its smelting furnaces at Copperhill, Tenn., which are now operated on the pyrite principle. It has been determined that these gases average about 6 per cent in sulphur dioxide, and when the plant is in full operation their quantity will enable the production of upward of 700,000 tons of sulphuric acid of 50° B. per annum.[4]

Other sources of sulphur are found in the spent oxides from gas works, the waste liquors of Le Blanc soda works and of ammonia works, and in petroleum, such as the oils of Lima, Ohio, and of Canada. According to Pennock,[5] the hydrogen sulphide recoverable from by-product coke ovens is sufficient, when oxidized, to supply nearly one-half the sulphuric acid required in converting the ammonia into sulphate. According to Mabery,[6] "probably 50 tons of sulphur daily is a conservative estimate of the amount extracted from Ohio oil and burned off into the atmosphere." The

sulphur may be obtained from sulphur bearing petroleum in the form of hydrogen sulphide which can be burned to sulphuric acid. This method is practiced to some extent in the United States, but until it becomes more general the product must appear in census statistics as being produced from sulphur.

The sulphur gases obtained by the burning of pyrites and other sulphurets are usually impure because of the other minerals naturally occurring in the ore. As pointed out in the report for 1900, in the contact process there described, these gases are purified before being brought into the presence of the contact mass. In the chamber process it has been customary to use these gases as produced and then to purify the sulphuric acid when it was specially desired. According to Schatterbeck,[1] several hundred tons of arsenic sulphide, which is obtained in our chemical works in purifying sulphuric acid, are thrown away every year in the United States, yet our imports of arsenic compounds have for several years past amounted to from 6,000,000 to 8,000,000 pounds, having a value of from $243,380 to $416,525.

In the Census report for 1900 it was pointed out that owing to the contact process for the manufacture of sulphuric acid having been made a commercial success by the Badische Aniline und Soda Fabrik, a formidable competitor to the long used chamber process had been developed. As a result, the period since 1900 has been marked by much activity in endeavors to improve the chamber process and to devise contact processes that are independent of the Knietsch process. The improvements in the chamber process consist largely in a reassembling, proportioning, and arranging of the chambers, with the introduction of dust chambers, fans, and intermediate towers, and the use of atomized water in place of steam. A notable departure from previous practice is found in the Meyer's tangent system. The chambers in this system are cylindrical in form, with the entrance pipe for the burner gases so placed that the gases enter the top of the chamber tangentially, and travel along the periphery in a downward spiral, leaving the chamber by an opening near the bottom. By this means a higher efficiency for unit volume of chamber is obtained, and greater compactness of plant results. Hence the cost of installation and interest, and the area required for the plant are materially diminished. According to Guttmann,[2] "the production of acid for a given chamber space is with ordinary chambers now frequently 3 kilos of H_2SO_4 per cubic meter, but with the intensified working one arrives at 4 kilos. With atomized water and fans in ordinary chambers 5.84 kilos have been obtained. A set of Meyer's chambers, without other improvements, produces 4 kilos. * * * With fans and atomized water a Meyer set will probably reach 8 kilos and more; at any rate the first chamber of the system, which is not worked to its full capacity, produces 10 kilos, and more." Further, in comparing the chamber processes with contact processes, he says: "The conclusion is therefore justified, that a factory burning about 100 tons of pyrites per week, and having a chamber plant, equipped with all recent improvements, can successfully compete with a contact plant for even the strongest sulphuric acid in the market."

According to Lunge,[3] there are six contact processes now in use, styled respectively, Badische, or Knietsch, Höchst, Grillo, Mannheim, Freiberg, and Rabe, about which, through patent specifications, publications, or special communications, considerable detail is known, and several others which have been kept secret. In the Badische, Höchst, Grillo, and Mannheim processes the conversion of SO_2 into SO_3 is rendered practically complete by contact action, while in the Freiberg and Rabe processes the contact action is supplemented by lead chambers for working up the residual gases. The Grillo process is known in this country as the Schroeder process. Of the processes named by Lunge, five appear to be in use in the United States—the Knietsch, Schroeder, Mannheim, Höchst, and Rabe, while the American inventions of J. B. F. Herreshoff are also used. The Knietsch was described at length in the report for 1900, and it may suffice to add that in this system the unit is one having a capacity for treating 5,000 tons of 50 per cent ore a year. The Schroeder process was made the subject of a symposium before the New York Section of the Society of Chemical Industry in February, 1903, and from the report[4] of this symposium it appears that the process is distinguished by the use of a contact mass composed of soluble salts, principally sulphates, carrying the platinum. According to this report the following advantages are claimed for this method:

(1) The contact mass is easily regenerated, hence the kiln gases do not need to be purified as perfectly as if working with platinized insoluble vehicles.

(2) The calcined crusts are very porous, so that the contact mass made from them offers much less resistance to the gases passing through them than the tightly packed asbestos formerly used.

(3) The catalytic action of the contact mass made from soluble salts is far superior to that of platinized insoluble carriers, and the contents of the platinum in the contact mass, which were from 8 to 10 per cent of the weight of the asbestos in the old Schroeder plates, have been decreased to one-tenth of 1 per cent without reducing the efficiency of the contact material.

At present (1903) there are 23 Schroeder plants built or building—7 in Germany, 2 in Russia, 1 in Poland, 1 in Italy, 2 in France, 1 in Chile, 1 in Mexico, 2 in South Africa, and 6 in the United States. Some are using blendes, some pyrites, some brimstone, and one a

low-grade gold ore. Some of the ores are quite free from objectionable impurities, while others are very impure, which necessitates different methods of purification.

The cost of the plant is less than that of a chamber and concentrating plant of the same capacity.

The advantage of the contact process is greater the stronger the acid made, the cost being the same per unit of sulphur for all strengths. For acid stronger than 60° B. it is cheaper than chambers; but for 50° B., and perhaps for 60° B., it has at present but little, if any, advantage.

One application of the process that promises to be of great importance is its use in connection with chamber plants to make strong acid, in place of concentrating in the usual manner. A plant is now being built for this purpose, and there is every reason to believe that it will show a marked economy, both in first cost and in operating expenses.

The Mannheim process was described by Wilke[1] before the New England Section of the Society of Chemical Industry in December, 1905, as follows:

This process is based on the following fundamental principles:

First. To use the heat of the ordinary roasting process for carrying on the catalytic action of the oxide of iron upon the sulphurous acid.

Second. The purification of the burner gases is a dry process. In all other processes the gases are washed and have to be dried again.

Third. The conversion or catalytic oxidation of that part of the sulphurous acid which passed through the iron contact, but had not been converted, is brought about by means of the waste heat of the burner gases.

Fourth. The whole process is carried on by moving the gases by means of exhausters only.

The roast gases leave the kilns at a temperature of about 700° C. This is the proper temperature necessary in the iron oxide to produce the conversion or catalytic action to transform the sulphurous acid into sulphuric anhydride. The iron oxide, at the above-mentioned temperature, forms iron arsenate, with the arsenious acid which is contained in the roast gases. If roast gases are taken at the temperature of the furnace through the oxide of iron, a large proportion of the sulphurous acid (50 to 60 per cent) is converted into sulphuric anhydride, while the arsenic contained in these roast gases combines with the oxide of iron.

Water contained in the gases to be converted reduces the catalytic property of the iron oxide. It is therefore necessary to produce the roast gases with dried air. The drying of the air necessary for the process is accomplished with sulphuric acid which is produced in the process.

The roast gases are produced in a furnace which is protected with an air-tight iron shell against any entrance of moist atmospheric air. The air necessary for the roasting process passes through towers which are scrubbed with sulphuric acid and is then conducted through air-tight pipes entering the furnace or kilns below the grate bars. The dry and hot roast gases so obtained are conducted to a shaft which is attached to the furnace and filled with oxide of iron (pyrites cinders). In this shaft part of the conversion takes place; that is, part of the sulphurous acid is converted into sulphuric anhydride, while at the same time the arsenic obtained in the roast gases is retained.

The roast gases therefore are subjected to a dry purification, and are considerably reduced in their contents of sulphurous acid. After the sulphuric anhydride which is formed in this first part of the process has been absorbed, the rest of the sulphurous acid contained in the gases can be converted into sulphuric anhydride by means of a very small amount of platinum. To do this, it is necessary to remove any small quantities of sulphuric acid (monohydrate) which have not been absorbed. This is accomplished by passing the gases through layers of porous material which is not affected by sulphuric acid. The main part of the sulphuric acid which is carried over mechanically is eliminated or retained in this way. The purified gases are now allowed to pass through layers of granulated basic blast-furnace slag.

The gases which have passed through the iron contact mass contain sufficient heat to reheat the filtered gases to the temperature necessary for catalytic action in the platinum contact.

It would be possible to utilize this heat by giving it off to the filtered gases. But the sulphuric acid (monohydrate) must be carried along in the form of vapor. The heat, therefore, must not be reduced too much to keep the monohydrate in a gaseous state. The heat given off in the heater located over the iron contact is not sufficient to raise the filtered gases to the temperature necessary to carry on catalytic action in the platinum contact. It is, therefore, necessary to have a small coal fire to raise these gases to their proper temperature.

The platinum contact apparatus must be built in such a way that it does not offer much resistance to the passage of the gases, in order to move them with an ordinary exhauster. This is accomplished by using a number of platinized asbestos nets, the meshes of which are such that the resistance in the whole apparatus does not represent more than the pressure of a column of water about 30 millimeters high. In constructing the platinum contact apparatus in this way, it is possible to exchange a single element during the process in the course of a few minutes without interruption. In this process it is possible to have a conversion of the roast gases up to 95 per cent.

The first plant in the United States was erected in 1903, in the works of the Schoellkopf, Hartford, and Hanna Company, in the city of Buffalo, N. Y. This plant consisted then of one unit with a capacity of about 1,600 tons of sulphuric acid or its equivalent. The original plant has since been enlarged to four times its original capacity. Besides this plant, four other firms have adopted this process, and there are now in use twenty-two units with a capacity of about 35,000 tons, and in the course of construction, ten more units with a capacity of 16,000 tons. This is a total capacity of over 50,000 tons per year. This has been accomplished in a little over two years since the process has first been introduced here.

This process does not require complicated or delicate pieces of apparatus, a staff of scientific men, nor any special apparatus for the purification of the roast gases, as this is done in the furnace itself. The amount of fuel consumed and motive power required is smaller than in any other known process, and the plant can be built up gradually on account of the units being small and being easily arranged in groups. The cost of repairs is very low.

According to Falding (V. Internationaler Kongress für Angewandte Chemie, 1904, vol. 1, page, 768), the following sulphuric acid plants were completed or in course of construction in the United States between 1900 and 1903:

Contact process plants.

NAME AND LOCALITY.	Process.
New Jersey Zinc Co., Mineral Point, Wis.	Schroeder.
New Jersey Zinc Co., Hazard, Pa.	Schroeder.
Peyton Chemical Co., Cal.	Schroeder.
Repauno Chemical Co., near Wilmington, Del.	Schroeder.
Dupont Powder Co., near Wilmington, Del.	Schroeder.
Harrison Bros. & Co., near Philadelphia, Pa.	Schroeder.
United Zinc & Chemical Co., Argentine, Kans.	Frasch converter.
—— Buffalo, N. Y.	Mannheim.
General Chemical Co., near New York, two plants.	(1)

[1] Journal of Society of Chemical Industry, 1906, vol. 25, page 4.

[1] Inquiry has developed the fact that the General Chemical Company is operating a large number of contact plants, and that as rapidly as its chamber systems wear out it is replacing them by contact plants. This company operates under the Herreshoff patents and it also owns and utilizes the Knietsch, Höchst, and Rabe patents. This company expresses great satisfaction with the working of its contact processes and finds that the acid thus produced from pyrites is substantially free from iron and is superior to brimstone acid in its freedom from arsenic.

Chamber process plants.

NAME AND LOCALITY.	Equipment.	Chamber capacity (cubic feet).

Virginia-Carolina Chemical Co., Greenville, S. C.		200,000

Sulphuric acid is probably used for a greater variety of purposes, especially in the chemical arts, than any other substance. According to Lunge,[1] the principal applications are the following:

I. *In a more or less dilute state* (say from 1·144° Tw. downwards). For making sulphate of soda (salt cake) and hydrochloric acid, and therefore ultimately for soda ash, bleaching powder, soap, glass, and innumerable other products. Further, for superphosphates and other artificial manures. These two applications probably consume nine-tenths of all the sulphuric acid produced. Further applications are for preparing sulphurous, nitric, phosphoric, hydrofluoric, boric, carbonic, chromic, oxalic, tartaric, citric, acetic, and stearic acids; in preparing phosphorus, iodine, bromine, the sulphates of potassium, ammonium, barium (*blanc fize*), calcium (*pearl-hardening*); especially also for precipitating baryta or lime as sulphates for chemical processes; sulphates of magnesium, aluminum, iron, zinc, copper, mercury (as intermediate stage for calomel and corrosive sublimate); in the metallurgy of copper, cobalt, nickel, platinum, silver; for cleaning copper, silver, etc.; for manufacturing potassium bichromate; for working galvanic cells, such as are used in telegraphy, in electroplating, etc.; for manufacturing ordinary ether and the composite ethers; for making or purifying many organic coloring matters, especially in the oxidizing mixture of potassium bichromate and sulphuric acid; for parchment paper; for purifying many mineral oils, and sometimes coal gas; for manufacturing starch, sirup, and sugar; for the saccharification of corn; for neutralizing the alkaline reaction of fermenting liquors, such as molasses; for effervescent drinks; for preparing tallow previously to melting it; for recovering the fatty acids from soapsuds; for destroying vegetable fibers in mixed fabrics; generally, in dyeing, calico printing, tanning, as a chemical reagent in innumerable cases; in medicine against lead poisoning, and in many other cases.

II. *In a concentrated state.* For manufacturing the fatty acids by distillation; purifying colza oil; for purifying benzene, petroleum, paraffin oil, and other mineral oils; for drying air, especially for laboratory purposes, but also for drying gases for manufacturing processes (for this, weaker acid also, of 140° Tw., can be used); for the production of ice by the rapid evaporation of water in a vacuum; for refining gold and silver, desilvering copper, etc.; for making organo-sulphonic acids; manufacturing indigo; preparing many nitro compounds and nitric ethers, especially in manufacturing nitroglycerin, pyroxylin, nitrobenzene, picric acid, and so forth.

III. *As Nordhausen fuming oil of vitriol* (*anhydride*). For manufacturing certain organo-sulphonic acids (in the manufacture of alizarin, eosin, indigo, etc.); for purifying ozokerite; for making shoe blacking; for bringing ordinary concentrated acid up to the highest strength as required in the manufacture of pyroxylin and other purposes.

It is of value to know the extent to which sulphuric acid is used in the more important industries in which it is employed, and an attempt has been made to ascertain this by an investigation of the data of the census of 1900. For purposes of comparison the various grades of acid occurring have been reduced to a common standard of 50° Baumé. The results of this investigation are set forth in Table 17.

TABLE 17.—*Quantity of sulphuric acid consumed for specific purposes: 1900.*

	Tons.
Total domestic production	1,548,123
Purposes for which consumed:	
Fertilizer manufacture	803,358
Petroleum refining	181,782
Pickling iron and steel	125,000
Alum manufacture	71,426
Mixed acids manufacture	63,059
Textile industry	50,000
Muriatic acid manufacture	48,750
Nitric acid manufacture	47,348
Acetic acid manufacture	17,814
Ammonium sulphate manufacture	13,908
Explosives manufacture	13,500
Blue vitriol manufacture	10,645
Epsom salt manufacture	2,773
Storage batteries	2,640
Tartaric acid manufacture	1,503
Iron liquors manufacture	1,220
Boric acid manufacture	707
Zinc sulphate manufacture	415
All other purposes	92,275

The first and largest item for the separate industries is the amount actually returned, as "materials used" and as "products consumed," by the fertilizer establishments. The second is estimated from the amounts reported[2] at the censuses of 1880, 1890, and 1905, since no report was recorded for 1900. The third is estimated from the statement of F. J. Falding,[3] in 1905, that "about 150,000 tons of 60° Baumé acid are used yearly in the iron and steel industry for pickling sheets, wire, etc., previous to galvanizing or tinning,

[1] Manufacture of Sulphuric Acid and Alkali, edition 1903, pages 1169 and 1170.

[2] Census of Manufactures, 1905, Bulletin 70, page 11.

[3] Journal of Society of Chemical Industry, 1905, vol. 25, page 403.

and this must contain less than 0.002 per cent of As." Most of the other figures were obtained by stoichiometrical calculation from the quantities of the given products returned. It has been the endeavor to make the estimates conservative and to avoid duplication. Possibly an error may exist in the item of alum, owing to the use of ammonium sulphate or of sodium sulphate from nitric or hydrochloric acid manufacture, or of natural potassium sulphate, in the manufacture of the product named, but the quantity of sulphuric acid required for the aluminum sulphate produced is large. It is to avoid duplication that certain industries, known to make use of large quantities of sulphuric acid, do not appear in the list. An example of this is found in the manufacture of dyestuffs, which is omitted, because the sulphuric acid of this industry is already accounted for in the nitric and mixed acids placed on the list. Accepting the figures of this list as fairly approximate, it appears that the sulphuric acid used in the fertilizer industry at the census of 1900 constituted 51.9 per cent of the total quantity of sulphuric acid produced in that census year. The sulphuric acid used in petroleum refining formed 11.7 per cent, and that used in pickling iron and steel 8.1 per cent, or these three industries together consumed 71.7 per cent of the total. This is lower than the estimates usually given, and may arise from the fact that in this investigation the acid of all grades has been reduced to a common basis, as the sulphuric acid used in the fertilizer industry is 50° Baumé acid, so that if the strong acid used in many other industries had not been so reduced for purposes of comparison, the acid used in the fertilizer industry would have appeared to form a larger percentage of the total.

Nitric acid.—Nitric acid, the second substance in this subclass, has been known from early times. The first description of its production, so far as is now known, appeared in 778, in the writings of Geber, who made it by distilling niter (potassium nitrate) with copper sulphate and alum. Raymond Lullius, in the thirteenth century, gave directions for making it by distilling niter with sulphate of iron. Soon afterwards Glauber obtained it by distilling niter with oil of vitriol. Nitric acid of 1.375 specific gravity, known as gilder's aqua fortis, and made by this method, sold in England in 1771 for 57 cents per pound. Nitric acid was manufactured at Philadelphia by Carter and Scattergood in 1834. It is to-day made commercially by distilling sodium nitrate with sulphuric acid, though other methods are now competing for recognition.

The quantity and value of the total amount of nitric acid manufactured, including that produced as a subsidiary product and that produced and consumed in the same establishment, was ascertained at the census of 1900, the value assigned that produced and consumed in the same establishment being the average value per unit for that reported for the acid produced for sale. Proceeding in the same way for the census of 1905, a comparison may be instituted between the returns for each census. This is shown in Table 18.

TABLE 18.—*Nitric acid—quantity and value of products: 1905 and 1900.*

	CENSUS.		Increase.	Per cent increase.
	1905	1900		
Quantity, pounds	[1] 108,380,387	[2] 63,084,722	45,295,665	71.8
Value	$5,232,527	$2,964,700	$2,267,827	76.5
Value per pound	$0.048	$0.047		

[1] Includes 62,116,206 pounds, with an assigned value of $2,981,583, consumed in establishments where manufactured.
[2] Includes 32,123,221 pounds, with an assigned value of $1,509,791, consumed in establishments where manufactured.

The increase in value per pound may have arisen from the increased cost of nitrate of soda, or from the fact that a larger quantity of the higher grade acid was produced. The Census form of inquiry does not specify the different grades of nitric acid, and all of those returned are embraced in a common total in the above statistics.

In 1900 it was estimated that to produce the total amount of nitric acid reported at that census there would have been required 43,841 tons of nitrate of soda and 47,348 tons of sulphuric acid, and there would have been 52,609 tons of niter cake produced as a by-product. Using the same proportions for the returns at the census of 1905, there would have been required 75,319 tons of nitrate of soda and 81,344 tons of sulphuric acid, and there would have been produced 90,383 tons of niter cake as a by-product. These results are necessarily but approximations, because, as mentioned above, the many different commercial grades of nitric acid are all combined in the figures used, and because the different methods employed give different yields.

TABLE 19.—*Nitric acid—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	41	38
California	7	4
Colorado	1	1
Connecticut	1	2
Illinois	1	1
Indiana	3	2
Kansas	1	.....
Massachusetts	3	3
Maryland	1	.....
Michigan	1	1
Missouri	.....	1
New Jersey	9	12
New York	4	4
Pennsylvania	6	4
Ohio	3	2
Rhode Island	.....	1

Table 19 shows a total gain of 3 establishments. At both censuses New Jersey ranked first and California second. Pennsylvania, which shared the second place with California and New York in 1900, in 1905 fell to the third place, while New York became fourth.

Nitric acid is usually manufactured by heating sodium nitrate with sulphuric acid in iron retorts. The reactions taking place are probably somewhat complex,[1] but the initial and final stages may be represented by the equations:

(a) $2NaNO_3+H_2SO_4=Na_2SO_4+2HNO_3$, or

(b) $NaNO_3+H_2SO_4=NaHSO_4+HNO_3$.

If the proportions of the materials used be such that the first equation holds, the temperature which obtains must be very high in order that it may be realized, and as a consequence the nitric acid produced may be partly decomposed before it leaves the retort. This results in a diminished yield, and a product high in nitrogen oxides, and therefore discolored. Moreover, the normal sodium sulphate which remains solidifies in the retort and is difficult to remove. If, on the contrary, the proportions of the materials be those indicated in the second equation, too much sulphuric acid would be required for economic operation, unless the nitric acid works were carried on in connection with soda or muriatic acid works where the sodium hydrogen sulphate could be used in a "salt cake" furnace.

As a rule the proportions of the materials put into the retort are such as to produce a mixture of the two sodium sulphates which remains liquid at the final temperature employed, so that, after the nitric acid has been formed and distilled from the retort, the niter cake may be run off from the retort.

The sodium nitrate used is purified Chile saltpeter containing, when dried, from 98 to 99 per cent of $NaNO_3$, and should be free from sodium chloride in order that the nitric acid may not be contaminated with hydrochloric acid. The sulphuric acid used differs with the strength of the nitric acid sought. For nitric acid above 1.38 specific gravity, 66° Baumé sulphuric acid is used; but for weaker grades, sulphuric acid from the lead pan evaporation, of about 1.7 specific gravity. The size of the charge employed in different factories varies necessarily with the quantity of acid required, but charges of over 2,000 pounds of nitrate with somewhat more than an equal weight of sulphuric acid are now not uncommon.

The retorts used most commonly have been cylindrical in form. They are set in a horizontal position and partly inclosed in brickwork above a grate. More recent forms approach the shape of a short cylinder or inverted cone. They are set in a vertical position and entirely inclosed in brickwork, so that the flame may play all about them. The horizontal retorts are provided with a manhole, and the vertical with a tube, through which the molten niter cake may be run off.

A system long used for condensing the nitric acid vapors from the retort is that of passing them through a series of air-cooled earthenware Woulfe bottles, or *bombonnes*, and finally to a coke tower, fed with water or concentrated sulphuric acid to dissolve the vapors which have escaped condensation. Usually no water is placed in the Woulfe bottles unless a weak acid is required. Sometimes the Woulfe bottles are arranged in step-like positions, called *en cascade*, so that the acid vapors may enter the system in the opposite direction from that in which the condensed acid is flowing down.

Guttmann has constructed a nitric acid condensing apparatus of vertical earthenware pipes, having very thin walls, and joined at the top by 180° bends of the same material. These pipes open at the bottom into a slightly inclined collecting pipe of earthenware, which is divided by diaphragms into sections joined by U-tubes passing under the diaphragms. These diaphragms force the acid vapors to pass up one pipe and down the next in order to traverse the system. The system of pipes may be air cooled or water cooled, and thereby the acid vapors are rapidly condensed. The inventor also introduces an injector, fed with compressed air, immediately behind the exit tube from the still, and thus the nitric acid vapors are rapidly drawn off and mixed with hot air.

Hart's condensing apparatus consists of a series of superposed glass or earthenware tubes, slightly inclined to the horizontal, which starts from one vertical standpipe and ends in another. Jets of water are allowed to play upon the tubes from above, which by evaporation cools the nitric acid vapors within the inclined tubes.

In the Greisheim process a reflux cooler, consisting of a Rohrmann stoneware worm immersed in water kept at a temperature of about 60° C. by the heat of the operation itself, is placed behind the retort so that the acid vapors are partly condensed, while the nitrogen oxides pass on to a tower where they are condensed or converted and recovered. Through this modification a very pure colorless nitric acid may be made in one operation.

Rohrmann and Lunge have devised plate towers, or columns, which take the place of coke towers, and consist of large stoneware cylinders filled with perforated plates of the same material, of such form and so disposed, one above the other, as to condense and concentrate rapidly the vapors rising in the column. Such towers are not only more efficient than coke towers, but, as coke reduces nitric acid, they give better yields.

Valentiner's process is one in which a vacuum is produced in the retort and condensing apparatus during the distillation of the nitric acid.

All of these processes are in use in this country in different establishments. The results of the operation of Valentiner's apparatus, which has been installed in this country since the taking of the census of 1900, are set forth in Table 20.

[1] Journal of American Chemical Society, 1900, vol. 23, page 489.

The first twelve distillations were made with niter and sulphuric acid of different strengths. The thirteenth was a distillation with niter and sulphuric acid, but charging at the same time some weak and dirty nitric acid. The fourteenth and fifteenth distillations were redistillations of weak and dirty nitric acid with sulphuric acid only. Ninety per cent of the yield was obtained as nitric acid of 93 to 96 per cent, with five-tenths of 1 per cent and less of nitrous acid. By redistillation in the same apparatus, the nitric acid was purified and concentrated to a strength of 96 to 98 per cent, with less than one-tenth of 1 per cent of nitrous acid.

Although for a long time sodium nitrate has been practically the sole commercial source of nitric acid, yet in the last five years many attempts have been made to obtain it in other ways. Ostwald has sought to produce it from ammonia and air by a contact process. This would necessitate a supply of cheap ammonia in order that the manufacture may be carried on profitably. Frank proposes to make this ammonia from calcium cyanamid prepared from atmospheric nitrogen.

The atmosphere in which the earth is enveloped consists of 79.2 per cent of nitrogen and 20.8 per cent of oxygen by volume. Its depth is such that, calculating from the pressure it exerts, it is estimated that the air existing above each acre of ground contains approximately 33,880 tons of free nitrogen. Naturally many have realized what important results would follow if a means could be devised by which this nitrogen could be made to combine with the oxygen with which it is intermingled in the atmosphere. As early as 1775 Priestley noted that nitrogen compounds were formed when electric sparks were passed through the air, and not long after Cavendish produced saltpeter by absorbing air, so treated, in caustic potash solution. Although many subsequent observations along this line were made by Berthelot, Lord Rayleigh, and many others, no method for accomplishing this end which appeared in the least promising was devised until Bradley and Lovejoy were, on September 30, 1902, granted United States patents for a method and apparatus. Their process, which was tried by the Atmospheric Products Company of Niagara Falls, N. Y., consisted in producing in the air a flaming electric arc of minimum volume by the rapid rotation of electrodes carrying high tension currents. While nitric acid was thus produced, the process proved too costly, and the experiments ceased.

Since then Birkeland and Eyde have devised a process which has been put into operation at Nottoden, Norway. In their device the flaming arcs produced by high tension currents are made to move to and fro through the atmosphere in the apparatus by exposure to the attraction of powerful magnets. This apparatus is characterized by a narrow air chamber through which air is passed, and within which the electrodes, placed near together, are arranged between the poles of a strong magnet and at right angles to these poles. A disk-shaped or deflected electric arc is thus obtained perpendicular to the lines of force of the magnetic field. Three such furnaces at Nottoden, using 500 kilowatts and 5,000 volts, give deflected arcs about 3 feet in diameter. This process has been operated on a very considerable scale. According to O. N. Witt,[1] the daily production now amounts to 1,500 kilos of anhydrous nitric acid, and an output of 500 to 600 kilos of nitric acid per kilowatt year can be regularly maintained. It is evident that Witt's figures simply set forth the nitric acid content of the product actually obtained, for the weak nitric acid which is directly produced in the atmosphere about the electric discharges must be combined with a basic radical in order to be recovered. For this purpose the nitrogen compounds formed are absorbed in water in towers, the weak acid being exposed repeatedly to the nitrogen oxides until it attains a strength of 50 per cent. The

[1] Journal of Society of Chemical Industry, 1905, vol. 28, page 699.

incompletely oxidized nitrogen oxides which leave the absorption towers are passed through milk of lime and then over quicklime, and are thereby converted chiefly into calcium nitrite. This is treated with the nitric acid, through which calcium nitrate is formed and nitrous acid set free. The latter is then oxidized to nitric acid and sent to the absorption towers. The calcium nitrate has been offered in commerce for use as a fertilizer, but, as the normal salt is extremely deliquescent and therefore troublesome, it is now converted into the more permanent basic calcium nitrate by the addition of more quicklime or of calcium sulphate. To obtain nitric acid of merchantable strength this calcium nitrate must be distilled with sulphuric acid, but there are difficulties in the way, such as the formation of calcium sulphate that is not easily fusible. Thus far no commercial nitric acid seems to have been formed by this process.

Notwithstanding that processes for the direct production of nitric acid from atmospheric nitrogen have not yet been made commercially successful, the necessity for other sources of supply is so pressing and increasing that this problem will probably be solved before the next census.

Niter cake, the by-product of this industry, is known also as "*sal enixum*," "Sally Nixon," and "cylinder cake." Its composition approaches that of sodium hydrogen sulphate or sodium bisulphate, but it frequently carries considerable adherent sulphuric acid. It generally contains from 25 to 30 per cent of "free acid" or "bisulphate acid," calculated as SO_3, and only traces of nitrate. Much of this material has in the past been thrown on the dumps, greatly to the injury of neighboring water courses and of surrounding vegetation, but it may be utilized in many ways. By fusing it with common salt the latter reacts with the excess sulphuric acid in the niter cake to form hydrochloric acid, which distills off and leaves the residue composed entirely of salt cake. By treating phosphate rock with niter cake, superphosphate, mixed with sodium sulphate, is produced. By reaction of a solution of niter cake in water with lime water, calcium sulphate, which may be used as a pigment in paint making or as a filler in paper making, is produced, together with Glauber's salt. Other instances occur in which the excess acid in niter cake may be used in substitution for the more costly sulphuric acid, and its use is extending.

Mixed acids.—Mixed acids, produced by mixing sulphuric acid with nitric, have been used in this country on a considerable commercial scale since the gun cotton and nitroglycerin industries were established, and their use has become common in other chemical industries. The statistics of this industry were reported separately only at the census of 1900 and at the present census. By assigning to the acid reported as produced and consumed the same value per unit as that found for the acid reported as produced for sale, the comparison set forth in Table 21 may be made.

TABLE 21.—*Mixed acids—quantity and value of products: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Quantity, pounds	[1] 140,668,959	[2] 135,610,095	5,058,864	3.7
Value	$4,142,147	$3,535,431	$606,716	17.2
Value per pound	$0.029	$0.026	.....	.....

[1] Includes 75,337,632 pounds, with an assigned value of $2,184,791, consumed in establishments where manufactured; and also the mixed acids produced in establishments engaged primarily in the manufacture of other products.
[2] Includes 93,241,276 pounds, with an assigned value of $2,424,273, consumed in establishments where manufactured; and also the mixed acids produced in establishments engaged primarily in the manufacture of other products.

The data presented in Table 21 show that this industry is steadily growing and that the larger part of the material is produced in establishments in which it is consumed in further manufacture. This fact tends to make it difficult to secure complete returns of the industry, for while manufacturers' books usually show records of the materials purchased, the stock on hand, and the products sold, they often may fail to show the materials produced and consumed in further manufacture. This may explain the decrease in amount of produced and consumed mixed acids that was returned at the census of 1905 as compared with that for 1900. The decrease, however, may be but partly due to this cause, for during the period since 1900 the practice of rebuilding the spent acids for further use has been greatly extended. Hence while from the standpoint of use and of the quantity of material nitrated the quantity of mixed acids employed may have increased largely, yet as the larger portion of this rebuilt acid is used over and over again, the total quantity used in the industry may have been less.

TABLE 22.—*Mixed acids—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	32	22
California	6	3
Connecticut	.....	1
Illinois	2	.....
Indiana	2	2
Kansas	1	.....
Massachusetts	1	4
Michigan	1	1
New Jersey	9	7
New York	7	1
Pennsylvania	1	1
Ohio	2	2

There has been an increase in the total number of establishments at the census of 1905 as compared with 1900 of 10, or 45.5 per cent. New Jersey has ranked first at both censuses, and is followed at the census of 1905 by New York and California in the order named. No other state has at this census shown more than two establishments.

Table 23 shows the distribution of this industry, based on the output of the different geographic divisions at the censuses of 1900 and 1905.

TABLE 23.—*Mixed acids—quantity of products, by geographic divisions: 1905 and 1900.*

DIVISION.	1905	1900
	Pounds.	*Pounds.*
United States	140,668,959	135,610,095
North Atlantic	96,400,122	49,834,129
North Central	29,400,758	31,055,966
Western	14,868,079	54,720,000

Although there was an increase of 46,565,993 pounds in the North Atlantic division, yet in the North Central and Western divisions there was a decrease due undoubtedly to the operation of the causes set forth above in the discussion of Table 21.

Mixed acids, as used in the various industries and for different purposes, vary in their relative contents of nitric and of sulphuric acid. As an example there may be cited the following:

Percentage composition of various mixed acids.

MANUFACTURE.	H_2SO_4.	HNO_3.
Nitroglycerin	61.9	34.5
Gun cotton	78.6	21.0
Pyrocellulose	57.0	23.2
Pyroxylin for plastics	66.0	17.0
Pyroxylin for smokeless powder	56.0	29.0

These percentages are generally approximations, and the data are given in terms of real sulphuric and nitric acids. There are other compositions used in the coal tar dye industry and other industries, but by far the largest amount is consumed in the manufacture of nitroglycerin. It may therefore be fairly assumed that the average composition of the entire quantity of mixed acid is approximately 62 per cent of H_2SO_4 and 30 per cent of nitric acid, the remainder consisting of water, nitrogen oxides, and impurities. Proceeding in this way it would appear that at the census of 1900 there were used in the making of mixed acids 63,059 tons of 50° Baumé sulphuric acid and 20,342 tons of nitric acid, and that at the census of 1905 there were used for this purpose 65,411 tons of 50° Baumé sulphuric acid and 21,100 tons of nitric acid.

Mixed acids are manufactured by mixing sulphuric and nitric acids, of the strength and in the proportions required for the purpose to which the product is to be put. The mixture takes place in iron tanks, and is promoted by stirring with paddles or with compressed air.

The method of rebuilding, or regenerating, mixed acids, which is in use at the United States Naval Smokeless Powder Factory at Indian Head, Md., has been described by G. W. Patterson.[1] At this factory the acid is used in making a cellulose nitrate which must contain 12.5 per cent of nitrogen and be soluble in a mixture of two volumes of ethyl ether and one volume of 95 per cent ethyl alcohol.

The allowed limits of variation in this product are so small that every detail in the nitrating process requires to be carefully checked and accounted for. The exact strength of the nitrating acids is most important, and every batch of acid must conform to a certain standard. The acids used for the manufacture of this grade of nitrocellulose are a mixture of approximately 56 per cent of H_2SO_4, 29 per cent of HNO_3, and 15 per cent of H_2O. With such a mixture, it is the usual practice to regenerate the spent acids by the addition of a mixture of strong sulphuric and nitric acids, this mixture being given the name of fortifying acid.

* * * All handling of mixtures of nitric and sulphuric acid is carried on in cylindrical steel tanks, connected by heavy 2½-inch pipes, one pipe for receiving acid, the other for delivering. Iron cocks on these pipes control the flow of acid. Compressed air at 20 pounds pressure is used entirely for mixing and transfer of acid. The air pipes are 1 inch in diameter, and in tanks, where mixing is done, the pipe is extended inside the tank and along its entire length just clearing the bottom. The end of the pipe is plugged and a row of holes drilled in the underside of the pipe forms an air chamber of the pipe, allowing the air to escape along its entire length simultaneously. A tank 23 feet 6 inches long and 5 feet in diameter holds conveniently 42,000 pounds of mixed acid; one 35 feet long and 6 feet in diameter holds 90,000 pounds. Each tank is provided with a 1-inch vent hole through a flange in the top. When air pressure is to be applied to the tank this hole is closed by a wooden plug.

The tanks are arranged close together in a battery, two of the 90,000-pound tanks for spent acids; 8 of the 42,000-pound tanks for mixed acid, fortifying acid, and 98 per cent sulphuric acid; one 42,000-pound tank mounted on a platform scale as a weighing tank is connected by permanent 2½-inch pipe to the other tanks, as it is found that a 15-feet lead of pipe is sufficient to prevent any influence on the weighing.

Spent acid having been collected in a tank to the amount of 85,000 to 90,000 pounds, it is mixed by blowing air through it for one hour, sampled, and carefully analyzed. The proper quantities of fortifying acid and sulphuric acid or nitric acid, as the case may be, to be added, are calculated; 34,000 pounds of the spent acid are transferred to the weighing tank, and the other necessary acids are then transferred to the weighing tank. Air pressure is now put on the weighing tank and the whole charge transferred to a mixing tank, where it is mixed one hour by blowing air. Analyses of the mixed acid invariably agree with the calculation. Two important requirements are necessary for accurate work: (1) The weighing tank must have an inside air pipe to give a preliminary mixing and to entirely clear the tank of acid; (2) If less than one-half a tank of acid is being mixed, the circulation is not so good, and a longer time is required to mix the charge, up to one hour and a half or two hours. An air pressure of 20 pounds will transfer 1,000 pounds of acid per minute.

* * * The number of times that a spent acid may be regenerated appears to be unlimited, provided the amount of N_2O_4 does not exceed the limit of 5.5 per cent. The acid at present in use in the factory has been regenerated at least 150 times and remains practically unchanged. The amount of suspended nitrocellulose in the spent acid under normal conditions is less than 0.01 per cent, while the total iron present calculated as Fe is only 0.025 per cent. During the winter months there is a slight but constant decrease in lower oxides in the spent acid, while in the summer months they increase. The nitrocellulose in suspension in mixed acids is continually decomposing, and if allowed to stand undisturbed, entirely disappears.

* * * The fortifying acid contains 44 per cent H_2SO_4, 48 to 49 per cent HNO_3, and 0.2 to 2 per cent N_2O_4, with a total acidity of 94 per cent. In preparing this acid, the precaution is taken to have a

[1] Bericht V. Internationaler Kongress für Angewandte Chemie, 1904, Vol. II, page 474.

sufficient amount of nitric acid contained, so that no nitric acid, as such, must be added to the spent acid for regeneration. It is analyzed by the same methods as are used for other mixed acids, and must contain only traces of chlorine and no metallic salts, except salts of iron. This acid is handled and treated in exactly the same way as mixed acids of less strength.

Class I. B.—Other Acids.

The subclass "other acids" includes all of the substances appearing in commerce which are styled acids by the chemist, except sulphuric, nitric, and mixed acids. At the census of 1900 the quantities and values of the hydrochloric, boric, acetic, tartaric, tannic, and gallic acids reported were set forth separately. The quantities and values of the lactic and citric acids reported were combined in the presentation, since there were less than three independent establishments reporting these products. As our industries expand and become more diversified, the number of different acids for which returns may be separately published will undoubtedly increase, for new and useful purposes to which they may be applied in the arts are frequently being discovered.

Table 24.—*"Other acids"—comparative summary, with amount and per cent of increase: 1905 and 1900.*

	Census.		Increase.	Per cent of increase.
	1905	1900		
Number of establishments	11	13	[1] 2	[1] 15.4
Capital	$4,857,350	$2,360,787	$2,496,563	105.8
Salaried officials, clerks, etc., number	123	69	54	78.3
Salaries	$208,316	$90,440	$117,876	130.0
Wage-earners, average number	692	446	246	55.2
Total wages	$428,989	$265,715	$163,274	61.4
Miscellaneous expenses	$203,390	$69,770	$133,620	191.5
Cost of materials used	$1,605,649	$945,955	$659,694	69.7
Value of products	$2,726,487	$1,848,348	$878,139	47.5

[1] Decrease.

From Table 24 it appears that though there has been a decrease in the number of principal establishments in this subclass, due probably to the products being more frequently manufactured in establishments where other substances having a larger value are also produced, yet in every other item there has been a marked increase. The percentage of increase in miscellaneous expenses and cost of materials has been far greater than in value of products; and the percentage of increase in salaries much greater than that in wages.

Muriatic acid.—Muriatic acid, in some respects the most important member of this subclass, has been known also as spirit of salt, chlorhydric acid, and hydrochloric acid. It is a solution of hydrogen chloride, HCl, in water, and occurs in commerce in various strengths. Basil Valentine, in the fifteenth century, was the first to describe its preparation, producing it by heating a mixture of common salt and green vitriol, although Geber, whose work was accomplished in the second half of the eighth century, made use of *aqua regia*, which is a mixture of hydrochloric and nitric acids. It is a curious point in chemical history that muriatic acid, which at present is so cheap, and which has at times been considered almost worthless, was in Glauber's time (1604 to 1668) the most costly of the mineral acids.[1]

The condition of the muriatic acid industry as such is ascertained by combining the returns from all establishments in which it was manufactured either as a principal or subsidiary product together with the figures for that consumed in further manufacture, the latter being given the same value per unit as was found for the former. The results are set forth in Table 25.

Table 25.—*Muriatic acid—quantity and value of products: 1905 and 1900.*

	Census.		Increase.	Per cent of increase.
	1905	1900		
Quantity, pounds	[1] 188,538,396	[2] 134,229,012	54,309,384	40.5
Value	$1,730,231	$1,173,900	$556,331	47.4
Value per pound	$0.009	$0.009	.....	.....

[1] Includes 61,035,714 pounds, with an assigned value of $549,321, consumed in establishments where manufactured; and also the muriatic acid produced in establishments engaged primarily in the manufacture of other products.
[2] Includes 17,553,903 pounds, with an assigned value of $157,985, consumed in establishments where manufactured; and also the muriatic acid produced in establishments engaged primarily in the manufacture of other products.

The marked increase shown in the amount produced and consumed indicates that in this industry, as in those previously discussed, there is a healthy tendency to realize the profit which accrues from further elaboration of the products of a chemical industry.

The quantity of muriatic acid given in the table includes all grades. The ordinary muriatic acid of commerce contains 40 per cent by weight of dry hydrogen chloride. Assuming the entire product reported in 1900 to be of this grade, there would have been required for its production about 41,427 tons of common salt and 54,582 tons of 50° Baumé sulphuric acid, while there would have been produced 52,624 tons of salt cake. For the quantity returned in 1905 there would have been required 59,700 tons of salt and 78,659 tons of 50° Baumé sulphuric acid, while there would have been 75,836 tons of salt cake produced. The above calculation is based on the further assumption that the acid was produced entirely by the action of sulphuric acid on common salt, for if niter cake were used with the common salt it would not only replace the sulphuric acid, but also a part of the salt required for the production of the quantity of salt cake desired. No definite information is at hand as to the extent to which niter cake is used in this industry, but there are indications which suggest that upward of 20 per cent of the common salt may be thus replaced, and of course a lesser amount of sulphuric acid.

[1] E. von Meyer, History of Chemistry, 1891, page 507.

TABLE 26.—*Muriatic acid—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	[1] 36	[2] 31
California	4	3
Colorado	1	1
Connecticut		1
Illinois	1	3
Indiana	1	2
Kansas	1	
Maryland	1	
Massachusetts	3	2
Michigan	3	1
Missouri		1
New Jersey	5	6
New York	5	4
Pennsylvania	9	5
Ohio	2	2

[1] Includes 25 establishments engaged primarily in the manufacture of other products.
[2] Includes 18 establishments engaged primarily in the manufacture of other products.

From Table 26 it appears that there has been an increase of 5 in the number of establishments, or 16.1 per cent. Pennsylvania, which was second in rank in 1900, passes to the first place, while New York, which was third, now shares second place with New Jersey, which was first in 1900. California now ranks third. No other of the states reports more than 3 establishments.

Table 27 shows the geographic distribution of the industry according to the quantity of the output at the censuses of 1900 and 1905.

TABLE 27.—*Muriatic acid—quantity of products, by geographic divisions: 1905 and 1900.*

DIVISION.	1905	1900
	Pounds.	*Pounds.*
United States	188,538,396	134,229,012
North Atlantic and South Atlantic	121,125,924	89,257,974
North Central	61,861,453	37,495,038
Western	5,551,019	7,476,000

From Table 27 it appears that there has been an increase in every one of the divisions presented except in the Western. There appears no evident cause for this exception.

Muriatic acid is manufactured by heating common salt with sulphuric acid or with niter cake. The roasting is carried on in salt cake furnaces of either the form known as the "open roaster," which consists of a cast-iron pan and a reverberatory hearth, or the "closed roaster," in which the pan and hearth are inclosed in a brick or fire clay muffle in order to prevent the soot and dust from the fire reaching the acid vapors and mingling with them. During the second stage of the process, when sulphuric acid is used, or throughout it, when niter cake is used, the charge must be constantly stirred to prevent "crusting," or adhering to the hearth. This has been accomplished by the use of a "rabble" worked by hand, but in the more modern Mactear furnace it is effected by a mechanical device. The acid vapors are absorbed in water. Formerly, and to-day still to some extent, this was done by the passage of the vapors through Woulfe bottles, placed *en cascade* and leading to a coke tower. The Lunge-Rohrmann plate tower will largely replace both, especially when combined with long cooling pipes exposed to the air, so that the vapors may be cooled before coming in contact with the water. A recent device for absorbing the vapors is found in the Cellarius tourill, or jar.

The results of a year's run with air cooling, using salt containing from 97 to 98 per cent of sodium chloride, is shown in Table 28.

TABLE 28.—*Muriatic acid produced with Cellarius jars during a twelve months' run.*

MONTH.	Salt (pounds).	20° acid produced (pounds).	Yield per 100 pounds of salt.
September	205,926	431,992	209.8
October	229,416	456,156	198.8
November	215,309	397,370	184.6
December	213,688	412,660	193.1
January	250,654	490,490	195.7
February	197,802	390,337	197.3
March	187,160	355,605	190.0
April	101,560	190,740	187.8
May	245,858	469,396	190.9
June	226,311	442,054	195.3
July	210,080	405,556	193.0
August	218,196	416,699	191.0

Acetic acid.—Acetic acid, as considered in the census returns, does not include the dilute acetic acid, produced by the fermentation of diluted alcoholic liquids or by the oxidation of alcohol, and known as vinegar. The grades of acetic acid found in commerce contain from 28 to 90 per cent of real acetic acid, and, unlike the other liquid acids in commerce, it is graded by its real acetic acid contents instead of by its specific gravity, because a 50 per cent solution of acetic acid possesses about the same specific gravity as anhydrous acetic acid.

This acid, in the form of vinegar, was known to the ancients. It is mentioned by Moses in Numbers vi, 3. Hippocrates employed it in medicine. Hannibal is said to have softened rock by fire and vinegar during his passage over the Alps. Acetic acid in its more concentrated form was known to Geber and to Stahl as being produced by the distillation of verdigris, which is an acetate of copper. It is to-day made by distilling brown or gray acetate of lime with concentrated muriatic acid, or sodium acetate with sulphuric acid.

TABLE 29.—*Acetic acid—quantity and value of products: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Quantity, pounds	[1] 29,506,021	[2] 27,875,222	1,630,799	5.9
Value	$597,235	$446,326	$150,909	33.8
Value per pound	$0.02	$0.016		

[1] Includes 2,431,741 pounds, with an assigned value of $28,635, consumed in establishments where manufactured; and also acetic acid produced in establishments engaged primarily in the manufacture of other products.
[2] Includes 1,214,667 pounds, with an assigned value of $19,434, consumed in establishments where manufactured; and also acetic acid produced in establishments engaged primarily in the manufacture of other products.

This comparison shows that the acetic acid industry is characterized by the same tendency as that pointed out in industries already presented, for while the increase in the total quantity of acetic acid is but 5.9 per cent, the increase in that produced and consumed is 100.2 per cent.

TABLE 30.—*Acetic acid—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	12	14
Illinois	.....	2
Maryland	1	.....
Massachusetts	3	2
Missouri	.....	2
New Jersey	5	2
New York	1	3
Pennsylvania	2	3

From Table 30 it appears that the number of establishments returned as producing acetic acid was smaller by 2 in 1905 than in 1900. Nevertheless both the quantity and value of the product for 1905 were larger than for 1900.

All other acids.—Table 31 contains the returns for all acids not already presented, by quantity and value, for the censuses of 1905 and 1900.

TABLE 31.—*Minor acids—number of establishments and quantity and value of products: 1905 and 1900.*

ACID.	1905			1900		
	Number of establishments.	Quantity (pounds).	Value.	Number of establishments.	Quantity (pounds).	Value.
Boric	7	6,956,896	$527,190	3	2,684,935	$198,212
Citric	4	2,265,631	598,718	[1] 3	[1] 3,886,382	[1] 335,297

Other acids[5]	7	.....	975,551	11	.....	1,151,819

[1] Includes lactic.
[2] Included in citric.
[3] Less than 3 establishments; included in "other acids."
[4] None reported.
[5] Includes gallic, salicylic, stearic, and tartaric acids in 1905 and 1900, and phosphoric and oleic acids in 1900.

The figures of Table 31 are only for acids produced for sale and do not include such as were consumed where produced.

The statistics for acids imported from 1891 to 1905 are given in Table 32. The data have been compiled from Commerce and Navigation of the United States, published by the Bureau of Statistics.

CLASS II.—SODAS.

This class comprises soda ash, including white alkali and refined alkali; sal soda, including natural soda, mild mineral alkali, soda crystals, washing soda, and crystallized sodium carbonate; bicarbonate of soda, including bread soda, saleratus, sodium bicarbonate, and sodium hydrogen carbonate; caustic soda, including soda lye and sodium hydroxide; and borax, including borax glass, lime and sodium borates, and sodium biborate. Salt cake, or anhydrous sodium sulphate, and sodium silicate may be included here when products of a soda establishment. In addition to the original establishments, there are those in which soda ash is converted into sal soda and bicarbonate of soda, and those of the compounders or packers who give an added value to soda lye or the carbonate.

The term "soda" has acquired in use a variety of meanings. In the laboratory the term has been used in the past to designate the sodium oxide or hydroxide. In technology it has long been used to designate the normal sodium carbonate; yet the mixture of normal and acid carbonates found in nature is styled natural soda, and the industry in which soda ash, normal and acid sodium carbonates, and caustic soda are manufactured is called the soda industry.

Soda was known to the ancients and was used by them in making glass. They may have obtained it in the form of natural soda, for this exists in the waters of many lakes or in the residues from them. Up to a recent date[1] 5,000 tons of natural soda have been exported annually from Alexandria, Egypt. Or they may have obtained it by extracting the ash of seaweeds and marine plants with water and evaporating to dryness. These remained the only sources of soda until the latter part of the eighteenth century, when Le Blanc, stimulated by a prize offered by the French Academy about 1775, followed out the proposal of Duhamel de Monceau to prepare soda from common salt. This he accomplished by acting upon the salt with sulphuric acid, obtaining hydrochloric acid and sodium sulphate, and then converting the sodium sulphate into carbonate by fusing it with lime and coal. This process became established on a sound commercial footing when introduced into England by Losh in 1814.

[1] Wagner's Manual of Chemical Technology, 1892, page 309.

At the time the Le Blanc process was before the French tribunal, it was placed in competition with a process offered by Fresnel, which was based on the reaction taking place when a solution of common salt is brought in contact with a solution of ammonium carbonate, by which sodium hydrogen carbonate, or bicarbonate of soda, and ammonium chloride are formed; but Fresnel's process was rejected because at that time no method for the recovery of ammonia was known. It was revived by H. G. Dyar and J. Hemming in England, about 1838, and was tested on a considerable scale, but failed of success because of mechanical difficulties. These were finally overcome by Ernest Solvay, a Belgian, who made the process a commercial success in 1863. To-day the Le Blanc and Solvay processes are the chief sources of soda, though some is made from cryolite, and caustic soda is obtained in the electrolysis of common salt.

Saleratus, which is bicarbonate of soda, was reported at the census of 1860 as being manufactured in this country in 11 establishments, the product having a value of $1,176,000. For 1870, 4 establishments were returned, with a product valued at $231,647. At the census of 1880 and at each subsequent census the statistics for soda products have been made a feature in the special report on chemicals and allied products.

Table 33 shows an actual increase for 1905 over 1900 in every item. The increases in capital and value of products were especially noteworthy, being over $7,000,000 in each case, while the increase in value of products was more than double that in cost of materials. The largest proportional increase was in miscellaneous expenses, while the next largest was in number of salaried officials.

TABLE 33.—*Sodas—comparative summary, with amount and per cent of increase: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Number of establishments	39	38	1	2.6
Capital	$22,728,369	$14,951,960	$7,776,409	52.0
Salaried officials, clerks, etc., number	784	370	414	111.9
Salaries	$1,046,801	$521,402	$525,399	100.7
Wage-earners, average number	5,961	5,788	193	3.3
Total wages	$3,310,216	$2,503,203	$807,013	32.2
Miscellaneous expenses	$2,150,469	$979,759	$1,170,710	119.5
Cost of materials used	$8,255,037	$5,331,823	$2,923,214	54.8
Value of products	[1]$18,466,504	[1]$11,073,406	$7,393,098	66.8

[1] Includes "all other products."

Table 34 shows that from 1880 on there has been a steady growth in both the quantity and value of the sodas produced. The percentage of increase in quantity was, up to 1905, greater than that in value, but at the present census this condition was reversed. In the figures for 1905 and 1900 borax and "all other products" were omitted from the list in order to make the statistics fairly comparable with those for the earlier censuses.

TABLE 34.—*Sodas—quantity and value, with per cent of increase: 1880 to 1905.*

CENSUS.	Number of establishments.	Quantity (tons).	Value.	PER CENT OF INCREASE.	
				Quantity.	Value.

Tons	518,954	390,603	47,400	128,351	471,554	32.9	994.8
Value	$8,204,545	$4,859,656	$1,179,720	$3,344,889	$7,024,825	68.8	595.5

[1] Less than one-tenth of 1 per cent.

[2] Decrease.

The figures of Table 35 show that, while there was an increase in the total quantity and value of sodas produced at each census as compared with the previous one, there was at the census of 1900, as compared with that of 1890, a decrease in the total value of the bicarbonate of soda and also in the quantity and value of the sal soda. At the census of 1905 there was a decrease in the value of the bicarbonate of soda, and in both the quantity and value of the sal soda. These decreases are largely due to the increased use of these

substances in the establishments in which they are produced. In such a summary as Table 35, if the produced and consumed products were included, the figures would be duplicated, for the other sodas are as a rule produced from the bicarbonate or the soda ash. Therefore, with the increased practice of soapmakers, wood pulp manufacturers, and others of causticizing soda ash and using the caustic soda produced in the manufacture of soap or wood fiber, the quantity produced for sale would be likely to be reduced. As explained in the report for 1900, the decrease in the production of sal soda is due to the increasing use of soap powders and other specially prepared washing materials.

At the census of 1890 sodas manufactured from natural soda were reported to the amount of 10,964,390 pounds, having a value of $124,783; and at the census of 1900, 20,420,000 pounds, valued at $106,600. At the census of 1905 the number of establishments reporting was not sufficient to permit of the statistics being published separately, but they are incorporated with soda ash in the data of Tables 36 and 37 for each census enumerated.

At the census of 1900, 7 establishments reported a product of 11,756,000 pounds of borax, having a value of $541,160. At the census of 1905, 7 establishments reported 41,764,000 pounds of borax, having a value of $2,122,808. This does not include the borax which was produced and consumed in the same establishments in the further manufacture of boric acid or other products.

TABLE 36.—*Sodas—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	63	[1] 55
California	6	6
Colorado	1	.....
Illinois	4	4
Indiana	3	2
Kansas	1	.....
Maryland	1	1
Massachusetts	3	1
Michigan	5	3
Missouri	2	2
Montana	1	.....
New Jersey	7	3
New York	9	12
Nevada	2	5
Ohio	4	1
Pennsylvania	8	9
Rhode Island	.....	1
Virginia	1	1
Wisconsin	4	4
Wyoming	1	.....

[1] Includes 5 establishments producing "soda products," but no "sodas."

From Table 36 it appears that at the census of 1905 as compared with the census of 1900, the establishments of the soda industry have increased 8 in number, or 14.5 per cent. The relative positions of New York and Pennsylvania remained unchanged in 1905, the former still ranking first and the latter second among the states. New Jersey, however, advanced from seventh to third place, with California fourth and Michigan fifth. No other state or territory reported as many as 5 establishments in 1905.

TABLE 37.—*Sodas—value of products, by geographic divisions: 1905 and 1900.*

DIVISION.	1905	1900
United States	[1] $19,785,385	[1] $10,922,536
North Atlantic and South Atlantic	10,512,852	6,559,295
North Central	8,745,382	3,694,436
Western	527,151	668,805

[1] Includes products other than sodas reported by establishments engaged primarily in this industry; and also the sodas produced by establishments engaged primarily in the manufacture of other products.

The figures of Table 37 show an increase in the value of sodas in all divisions shown except in the Western, the greatest increase being in the North Central. The decrease shown in the Western division can not be accounted for except perhaps by the fact of the existence of small establishments working natural soda or borax deposits as neighborhood industries, which would not under the rule be included in the establishments enumerated at the last census.

Up to the date of the commercial success of the Le Blanc process for making soda, potash, or "vegetable alkali," was much cheaper and more largely used than soda, or "mineral alkali." Since the development of the Le Blanc process the reverse has held true. Singularly, notwithstanding that the United States has been a large consumer of sodas, and that muriatic acid, and, on further treatment, chlorine and bleaching powder, are side products of the Le Blanc process, it never secured a firm foothold in this country.

The ammonia-soda process, on the other hand, has become a factor in our industries. The first to experiment with this process in the United States were Herman and Hans Frasch, who located a plant at Bay City, Mich., about 1880, but the enterprise was not a success and the plant was abandoned some two or three years later. In 1881 the Solvay Process Company, of Solvay, near Syracuse, N. Y., and Delray, near Detroit, Mich., was organized under the laws of the state of New York. According to Pennock,[1] the following plants in the United States were in 1900 engaged in manufacturing sodas by chemical methods as distinguished from electrolytic methods: The Solvay Process Company at Syracuse, N. Y., and Detroit, Mich.; the Michigan Alkali Company at Wyandotte, Mich.; the Mathiesson Alkali Company at Saltville, Va.; and the Pennsylvania Salt Company at Natrona, Pa. Between 1900 and 1903 the plant of the Columbia Chemical Company was installed at Barberton, Ohio, and the Frasch process at Cleveland, Ohio. All of these plants used the ammonia-soda process except the Pennsylvania Salt Company, which produced its sodas from cryolite.

In the operation of the ammonia-soda process a purified and concentrated salt brine is saturated with ammonia. This brine is then sent through iron

[1] Bericht V. Internationaler Kongress für Angewandte Chemie, 1904, vol. 1, page 661.

towers, where it encounters carbon dioxide gas, resulting in the formation of bicarbonate of soda, which separates out in crystals, while the liquid containing the ammonium chloride formed by the reaction, together with some ammonium carbonate and the residue in the brine, passes on and is collected for subsequent use.

The bicarbonate of soda, after wringing and washing in a centrifuge, is dried in an atmosphere of carbon dioxide and may be sold as bicarbonate, or it is calcined and converted into soda ash. When the soda ash is dissolved in warm water and the hot solution is allowed to stand until all sediment is deposited, large crystals of quite pure sal soda will be deposited as the solution cools. If the soda ash solution be treated with lime water, calcium carbonate will be formed and precipitated, while sodium hydroxide or caustic soda will remain in solution and may be obtained as a solid by evaporation of the solution. In the Hewitt and Mond, or Loewig's process the soda ash may be fused with iron oxide forming sodium ferrate, which is easily decomposed by warm water into caustic soda and ferric oxide. Pure iron ore or pyrites cinder may be used in this process.

Since the common salt used in the ammonia-soda process must be in solution, natural brine supplies this requirement in the most economical way. By reference to the bulletin on salt it will be noticed that most of the establishments cited above from Pennock's article are located near salt deposits, where natural salt brine, or that formed by sinking shafts to salt deposits and dissolving the salt in place, is cheaply obtained.

Since ammonia is so largely used in this industry, soda works are frequently operated in conjunction with by-product coke ovens. Much of the combined and free ammonia in the liquid running off from the bicarbonate of soda crystals in the carbonating tower is, however, recovered for further use by heating the liquid alone or with lime. Such repeated utilization must be taken into account in any attempt to estimate the quantity of ammonia used in this industry.

The carbon dioxide used for carbonating is originally obtained by calcining limestone, but much of it is recovered when calcining the bicarbonate of soda to soda ash, and from the treatment of the ammoniacal solution from the carbonating tower. Carbon dioxide might be obtained from the burning of coke or coal, but as quicklime is needed both in caustic soda manufacture and in the ammonia recovery process, it is necessary to calcine limestone.

The lime is recovered partly in a salable condition, either as crystallized calcium sulphate, used as a filler in paper making and for weighting cloth, under the names of "crown filler" and "pearl hardening," or as calcium chloride, which is used in the brine tanks of ice machines.

In his address[1] before the Congress of Applied Chemistry, Ernest Solvay reviewed the history of the soda industry and presented the data for the total production of sodas from 1850 to 1902, set forth in Table 38, but with the metric tons converted into short tons and the francs into dollars.

TABLE 38.—*World's production of sodas: 1850 to 1902.*

YEARS.	Total quantity produced (tons).	Produced by the Le Blanc process (tons).	Produced by the ammonia process (tons).	Average selling price per ton taken at the factory in Europe.
1850	165,345	165,345	.....	$135.10
1863	330,690	330,690	.....	86.85
1864 to 1868	413,363	412,260	331	77.20
1869 to 1873	496,035	492,728	2,865	54.04
1874 to 1878	578,708	545,639	33,069	54.04
1879 to 1883	744,053	600,754	149,913	32.81
1884 to 1888	881,000	479,501	402,340	23.16
1889 to 1893	1,127,653	429,897	697,756	22.20
1894 to 1898	1,377,875	492,109	1,085,765	21.23
1902	1,940,048	165,345	1,744,703	21.23

Thorp describes the manufacture of sodas by the cryolite process as follows:[2]

The ground cryolite is mixed with powdered limestone, and calcined at a red heat. Carbon dioxide escapes, and a mixture of calcium fluoride, sodium oxide, and sodium aluminate remains. On lixiviating this mixture with water another sodium aluminate is formed and goes into solution, leaving the calcium fluoride as an insoluble residue. The solution of sodium aluminate is then decomposed according to the third reaction, by passing into it purified limekiln gases, or the furnace gases of the calcining operation. Hydrated alumina is precipitated, while sodium carbonate remains in solution. Sal soda may be made by evaporating the solution, and was formerly the chief source of bicarbonate for culinary and medicinal purposes. If carried to complete dryness and calcined, a high grade of soda ash is obtained. By causticizing, it yields a very excellent caustic.

The by-products aluminum hydroxide and calcium fluoride are used in the alum and glass industries, respectively.

Soda ash appears in the market as 58 per cent, dense 58 per cent, 48 per cent, special 48 per cent, and 36 per cent; caustic soda, as high test 76 per cent, 74 per cent, 70 per cent, special 70 per cent, 60 per cent, and special 60 per cent; soda crystals, as monohydrate crystals, 49.8 per cent, and snow flake crystals, 40.9 per cent; and bicarbonate of soda, as pure bicarbonate, 99 per cent, for baking soda, and anchor dust, which is an inferior grade used as a source of carbon dioxide in charging "soda water." The percentages refer to the Na_2O contents in each case except that of the bicarbonate, where it refers to $NaCO_3$. In the census returns no cognizance is taken of these many grades, so that the figures given for any item in the tables are the gross amount for all grades.

Sodas are used in glassmaking. Thus at the census of 1890[3] there were reported as used by this industry 96,777 tons of soda ash and 38,092 tons of salt cake; at the census of 1900, 157,779 tons of soda ash and 53,257 tons of salt cake; and at the census of 1905,[4]

[1] Bericht V. Internationaler Kongress für Angewandte Chemie, 1904, vol. 1, page 108.

[2] Outlines of Industrial Chemistry, 1905, page 96.

[3] Twelfth Census, Manufactures, Part III, page 983.

[4] Census of Manufactures, 1905, Bulletin 57, page 46.

215,462 tons of soda ash. They are used in soap-making, 53,777 tons of soda ash and 71,551 tons of caustic soda, having been reported as used in this industry at the census of 1905.[1] Soda ash, caustic soda, and salt cake are used in the treatment of wood in the manufacture of wood fiber. The statistics of consumption are not at hand, but at the census of 1900,[2] 94,042 tons, and at the census of 1905,[3] 120,978 tons of soda wood fiber were reported as having been purchased for use in paper making. According to Griffin and Little,[4] with indirect steam in rotaries, about 700 gallons of a liquor, containing from 6 to 9 per cent of NaOH, are used to a cord of wood, while upright digesters require considerably more. As the liquors from the digesters are treated so as to recover their soda contents for further use, it is difficult to estimate the quantity of sodas actually used in the wood pulp industry, but it is large. There is a great variety of other uses to which sodas are put, but the three industries named are the largest consumers.

The natural soda industry was described with much detail in the special report on chemicals and allied products at the census of 1900.

The borax industry is closely associated with the natural soda industry since both substances, or at least boron compounds from which borax may be obtained, are found as residues in arid regions. In fact, deposits of a mixture of natural soda, common salt, and borax are known in California as "borax beds." According to Bailey[5] borax was first discovered in the United States on January 8, 1856, by Dr. John A. Veatch, on evaporating water from the Tuscan springs, Tehama county, Cal. Bailey describes the development of the industry as follows:

> California in 1849 started the gold mining industry in the United States, and fifteen years later followed it with the establishment of the borax industry. The 12 tons made at Borax Lake, on the margin of Clear Lake, in Lake county, were the first produced on the American continent.
>
> The young industry thrived for the next four years, although the maximum output of 220 tons in one year would seem small now.
>
> The next three years, 1869, 1870, and 1871, were dark years for those watching the growth of the youngster, for the supply of the pure crystals in the blue mud of the famous little lake had given out, and an unruly artesian well had ruined the waters of the lake by diluting them beyond the profit point.
>
> The deposits of Lake Hachinhama, on the opposite side of Clear Lake, exhausted themselves in yielding 140 tons in 1872.
>
> The prospectors, however, had been aroused to interest in the mineral that was worth over $600 per ton and "only had to be shoveled up to be ready for the market," and discoveries in the deserts of California and Nevada followed each other with bewildering rapidity.
>
> In 1873 San Bernardino county began her big record with the production of 515 tons from the so-called borax "marshes," or the "dry lakes" of the desert. Inyo county soon followed in lively rivalry, and the high water mark of the early years was reached in 1876, when 1,437 tons were produced, worth at that time over $312,000. From 1880 to 1888 the production increased slowly but steadily from 609 to 1,405 tons in a year. The year 1887 saw the suspension of work on the "marsh" beds, and the establishment of works on "colemanite" or borate of lime ores, in the Calico district, San Bernardino county. Since the discovery of these beds, large establishments have been erected in Alameda, near San Francisco, at Marion and Daggett, and at Bayonne, N. J., for the treatment of borates, and the production has risen from 1,405 tons in 1888 to 25,837 tons in 1900. The discoveries in Kern and Ventura counties also led to the establishment of boric acid manufacturing by the Stauffer Chemical Works of San Francisco, and the making of borax by the Chas. Pfizer & Co. works of New York.
>
> When borax was first made in California, in 1864, the value of the refined article was 39 cents per pound, or $780 per ton. In spite of the discovery in Lake county, the price, while gradually declining, did not fall below 30 cents until 1873, when the borax "marshes" of San Bernardino county produced over 1,000,000 pounds, worth 24¼ cents per pound, or $496 per ton.
>
> The next year, 1874, saw the price fall to 14½ cents per pound, or $284 per ton, and the decline continued until 1879, when it stood at 9 cents per pound, or $180 per ton. From 1880 to 1883 the price varied from 12½ to 14¾ cents per pound, or from $245 to $295 per ton. Prices in New York varied more widely than on the Western coast, as may be noted from one incident of many that might be quoted. In January, 1883, a tariff law was enacted that went into force in July of that year. During this six months, while imports were free from duty, 2,500 tons of boric acid, equivalent to 3,500 tons of borax, were imported. This, added to the large accumulations of the home manufacturers, caused the price to drop to 4½ cents per pound in New York, or less than the cost of production.
>
> On the Coast, the result was that the producers combined and waited for living prices. From 1888 to 1894 the price stood still, practically, ranging from 6 to 7½ cents per pound, or from $120 to $150 per ton. Since that time the value of the refined article has been 5 or 6 cents per pound on the Coast, and about a cent higher in the East.
>
> Owing to the establishment of the immense works in New Jersey, the shipments to the East are mainly in the form of crude borates, worth from $20 to $35 per ton, according to purity. The depression in prices, owing to rivalry between companies competing for the market, has been done away with, and the industry has outlived the disturbing features incident to youth, and has finally settled to a more certain and stable basis.
>
> While the margin of profit is too small to permit the working of any but the most favorably located and economically handled deposits, yet the prevailing low prices are evidently causing an increased consumption of borates in the arts and manufactures in which they have been employed, and new uses are being continually found for the various compounds of boric acid. In this extended and ever growing consumption, the manufacturers find their compensation for low prices.

He further describes the process of preparing commercial borax as follows:

> Every year has seen some improvement made in the industry in the way of more perfect appliances and processes. The process at first used in Lake county consisted in boiling the borax and crystallizing it in small pans holding from 2 to 3 gallons each; and the plant that produced the first 12 tons in 1864 consisted of some 4,000 such pans. The processes at the period when the "marsh" beds were worked consisted of boiling the crude material in large iron tanks and then running the solution into wood or iron settling tanks, the crude borax obtained being purified by recrystallization.
>
> In the Calico district the colemanite ore is treated as follows at Marion: Low-grade ores, that were formerly rejected, are roasted in a Holthoff-Withey furnace, with two hearths having a capacity of 100 tons a day, six oil burners furnishing the heat. Colemanite when mildly heated is reduced to a fine powder, which is bolted, sacked, and shipped to the company's works at Bayonne, N. J.,

where the "flour" is boiled with soda to form borax. Any pandermite ore present is not affected by the heat and is lost in the waste, known locally as "dry bone." This waste often amounts to 50 per cent of the "flour" secured.

At Bayonne the huge machinery is driven by sets of independent electric motors. The crude colemanite reaches the works in sacks, as shipped from this state. It is first coarse-crushed on the ground floor of the works, and then conveyed to a Griffin mill, which reduces it to the fineness of flour. It is then carried by a screw conveyor to the foot of an elevator, which raises it to the first floor. Here it is dropped into a 100-ton tank and boiled with water. After boiling, it is drawn into settling tanks on the second floor, where the clear solution is run back to crystallizing vats on the first floor, the sediment being raised by a centrifugal pump to a tank on the third floor, and thence into a filter press of 50 pounds per square inch, the pulp receiving finally, however, double that pressure. The liquor drawn from the press goes back to the settling tank, and the refuse cakes go to the dump.

The crystallizing vats are of sheet iron 20 feet long by 6 feet wide and 6½ feet deep. Two-inch iron pipes are laid across the top of the vats, from which wires 5 feet long and 0.25 inch in diameter hang into the vats. As the solution cools, the borax crystallizes upon the wires and on the sides and bottoms of the vats. After crystallization, the mother liquor is pumped out and used again as a solvent, and the borax crystals removed. The crystallized borax is raised to the fourth floor to crushing rolls and screens and sorted into three sizes, viz: (1) Refined crystals; (2) refined screenings; (3) granulated borax. The granulated borax is then dried by hot air, in an inclined rotary cylinder; then pulverized in a cyclone pulverizer; then caught in dust chambers; and finally barreled for the market.

It is found that while the borax from the wires in the vat is pure, that from the sides and bottom has to be redissolved and refined.

The statistics of imports are from "Commerce and Navigation of the United States," published by the Bureau of Statistics, Department of Commerce and Labor.

CLASS III.—POTASHES.

The class of potashes comprises stone-ash (known also as crude potash and lump potash), which is a mixture of caustic potash, potassium carbonate, and potassium sulphate with organic and various kinds of inorganic matter; potash, or black salts, or black flux, which is the unrefined potassium carbonate produced by calcining stone-ash or argols, or wine lees; and pearlash, or white flux, which is refined potassium carbonate. The term "potash" has also long been used to designate caustic potash, known also as vegetable alkali, potassium hydrate, or hydroxide, but as here used the term is more comprehensive. Caustic potash is properly included here with the potassium carbonate, as caustic soda was with the sodium carbonates under "sodas." Were any potassium hydrogen carbonate or

bicarbonate of potash to be reported, the data for it would be entered under this class.

A detailed description of the American process for the production of potashes from the ashes of plants, together with a resumé of the processes in use abroad, and of those proposed for use in the production of potashes from various sources, was given in the special report on chemicals and allied products for the census of 1900. It is evident from the nature of the operations and the character of the materials used in the American process that, in a majority of instances, the industry is a neighborhood industry, and hence one which does not come within the scope of the census of 1905. Statistics for production, however, were taken within the states, and it therefore becomes possible to present their results in comparison with those presented separately at each census beginning with that of 1850. The quantity and value of the potashes reported at each census from 1850 to 1905 are set forth in Table 40.

TABLE 40.—*Potashes—quantity and value of products: 1850 to 1905.*

CENSUS.	Number of establishments.	PRODUCT.		Average price per pound.
		Pounds.	Value.	
1905	[1] 39	1,811,037	$104,655	$0.058
1900	[1] 67	3,864,766	178,180	0.046
1890	75	5,106,939	197,507	0.039
1880	68	4,571,671	232,643	0.051
1870	105	.....	327,671	.....
1860	212	.....	538,550	.....
1850	569	.....	1,401,533	.....

[1] Includes establishments engaged primarily in the manufacture of other products.

The statistics in Table 40 show a constant decrease in the total value of the product since 1850 and a steady decrease in the quantity of the product since 1890. This seems quite reasonable, in consideration of the destruction of the forests during recent years, and the resulting decrease in the quantity of ashes readily available for the manufacture of potashes; also in consideration of the decrease in the native fertility of the soil, with which has come an inclination to return potash to the soil as it occurs in the ashes rather than to extract and market it; and also in consideration of the cheapening of soda or hard soaps and increased facilities for bringing them to agricultural communities, whereby the temptation to extract potash from ashes for the manufacture of potash or soft soaps is lessened. These causes, combined with the comparative cheapness of foreign potashes, tend to destroy the domestic industry. The data of Table 40 indicate that the industry is a waning one, and that it may come to be of so slight importance as not to warrant separate consideration in subsequent censuses, unless other causes, recently set in operation, shall revive it in another form.

Although potassium occurs in considerable quantities in India saltpeter, in orthoclase feldspar, and in many other minerals which have long been used for many purposes in the arts, yet up to about the middle of the nineteenth century the ashes of plants were practically the sole source of supply of potashes. In the beginning of that century Stassfurt, in Germany, was noted for its salt works, in which salt was produced by the evaporation of natural brine obtained, by pumping, from driven salt wells. With the utilization of rock salt deposits in various localities the price of salt was reduced to such a point that the Stassfurt works ceased to yield their former large revenue to the Prussian Government, and with a view of making them again valuable the Government began boring for rock salt in this locality in 1839. In 1857 a shaft, which was begun in 1852, reached at a depth of 1,080 feet a stratum of rock salt, but in doing so it passed through a heavy deposit of so-called "abraumsalze," or refuse salts, which consisted largely of compounds of potassium and magnesium, which were then considered worthless.[1] This deposit is now, and has long been, the chief source of the potashes and the potassium salts of commerce. These native Stassfurt potash salts consist of the minerals carnallite, which is a magnesium potassium chloride; sylvite, which is potassium chloride; and kainite, which is a magnesium potassium chloride containing also magnesium chloride.

As early as 1861 patents were granted to A. Frank for the extraction of potassium chloride from the abraum salts, and since then a variety of processes of extraction have been invented and put into use. By treating this potassium chloride with sulphuric acid, limestone, and coal, as Le Blanc treated sodium chloride, potassium carbonate is obtained. By means of a process analogous to the ammonia-soda process, potassium chloride being used in place of sodium chloride and trimethylammonium carbonate in place of ammonium carbonate, potassium hydrogen carbonate, or bicarbonate of potash is obtained. By causticizing these carbonates with lime, caustic potash is obtained.

The Stassfurt deposit of potassium salts has been explored since its discovery and it has been found to cover an area of about 100 square miles. The stratum of carnallite, which is the most abundant and commercially most important, is from 50 to 150 feet in thickness. This deposit continues to be the chief source of the world's supply of potassium salts, except the nitrate, and the mining of them and their conversion into potashes and other commercial salts gives employment to a large force of men. It is stated that these German mines, and the chemical works connected with them, employ 10,000 miners, 15,000 laborers, and 800 chemists and technical experts, besides a large clerical force.[2]

Consideration is now being given to deposits of potassium salts within the territory of our own country, and this subject is discussed at length by William M. Courtis, who says:[3]

[1] Potash in Agriculture, The German Kali Works, page 5.
[2] Mineral Industry, 1907, Vol. XV, page 659.
[3] Ibid., page 663.

There are several large and well-known supplies of surface potash in this country, which could be utilized in the event of the imports of the United States being entirely cut off, but at present they are remote from railroads, in the desert portion of this country, and the cost of working would be prohibitive. These deposits are largely mixed with soda salts and would require washing, and this would be costly. The salts consist of sulphates and nitrates only, the chloride not having been found in any quantity. It is probable that with so many surface indications, occurring where conditions are similar to those of the Stassfurt district, boring on a large scale would supply information which would eventually lead to the discovery of a bed similar to that of Germany, but it would require a large expenditure for blind boring. However, in Germany the surface indications were so slight that the immense deposits were not discovered until a comparatively few years ago, and then only by accident.

Since the census of 1900 a new method for the manufacture of caustic potash from potassium chloride has been put in operation in this country. This is described as follows:[1]

The Roberts Chemical Company, of Niagara Falls, electrolyze potassium chloride. At the cathode caustic potash is produced and hydrogen is set free, while at the anode chlorine is set free. The quantities of hydrogen and chlorine are in equivalent proportions, so that they may be combined to form hydrochloric acid. This is done by the Roberts Chemical Company, the two products of which are, therefore, hydrochloric acid and caustic potash. In the September issue of Things Chemical, of the Charles E. Sholes Company, who are the sales agents of the Roberts Chemical Company, it is pointed out that on account of its method of production, this hydrochloric acid can not contain the ordinary impurities of muriatic acid unless they were expressly and intentionally added. Its only impurity is a small amount of free chlorine, which gives it a pale yellow color. The acid is of special interest to manufacturers of fine chemical products, gas mantles, cereals and foodstuffs (where there must be no arsenic), high grade and fancy leathers, and in general, for all purposes where quality is of more importance than a slightly increased first cost. The electrolytic caustic potash is made in three forms: Fused (solid), in drums of 100, 200, and 800 pounds; broken, in drums of 100, 250, 500, and 1,000 pounds; and caustic potash solution, in drums of 325, 650, and 1,350 pounds. The solid and broken grades analyze not less than 85 to 87 per cent KOH and 10 to 15 per cent carbonate and chloride of potassium. The solution contains 45 to 47 per cent KOH. Caustic potash is now very largely used in electroplating shops for removing grease from metallic surfaces before plating. In the laundry a dilute solution of caustic potash is an excellent "builder," for the soap will remove all grease and produces excellent suds, without injury to the fabric. Soapmakers use caustic potash especially for all the finest soaps, whereas caustic soda is used for the common grades.

Another direction in which the potash industry tends to develop is in the production of potashes from the potash or orthoclase feldspar and from other minerals containing potassium. Several inventions for the extraction of potash from these minerals have been patented, the latest patent, No. 851922, of April 30, 1907, having been granted Dr. Allerton S. Cushman, assistant director of the United States road material laboratory, for a process for the extraction of potash, soda, and other soluble bases from ground rocks. This is described as follows:[2]

Feldspathic or other potash bearing rock is ground to fine powder, slimed with water, and placed inside of a suitable wooden container, which is then set inside of another larger vessel. Water is now placed in the outer vessel and electrodes inserted, so that the inner or slime chamber becomes connected with the positive pole, and the outer chamber with the negative pole. A current of electricity from a dynamo is then turned on. When this is done the potash, soda, and other soluble bases are partially set free from the combinations with alumina and silica in which they exist in the feldspathic rocks.

Under the influence of electrolysis the soluble bases pass through the wooden partition and the water in the outer vessel becomes alkaline, owing to the accumulation of potassium and sodium hydroxide. The electrical resistance of the cells arranged in this way is so high that only a small fraction of an ampere passes through under a potential of 110 volts. After a certain percentage of the alkali has been extracted in this manner, the action slows down, and it has been found necessary to devise methods to accelerate the action.

Doctor Cushman has discovered two methods for accelerating the decomposition of the rock slime and hastening the extraction of the potash: (*a*) By a suitable grinding or churning arrangement the slime in the inner chamber can be kept in a continual agitation, which causes the necessary reactions to go on more rapidly. (*b*) If a small quantity of hydrofluoric acid is added to the slime a very great acceleration in the rate of decomposition and extraction is obtained, and it is possible in a reasonably short time to make a complete extraction of all the potash contained.

If instead of caustic potash it is desired to make various salts of potash such as are in ordinary use for fertilizers and other purposes, that is, nitrate, sulphate, chloride, and phosphate, the corresponding acids—nitric, sulphuric, hydrochloric, and phosphoric—are fed in a dilute form into the outer or so-called cathode chamber, fast enough to neutralize the caustic alkali as it forms. By varying the amount of acid added, the resistance of the cell can be controlled and the decomposition of the rock carried on under the best and most economic conditions.

The consumption of potash or pearlash in the glass industry of the United States was, at the census of 1890,[3] 2,544,978 pounds, valued at $135,047, and at the census of 1900,[3] 4,406,211 pounds, valued at $186,847. The quantity of potash used in the soap industry at the census of 1905 [4] was 4,453,800 pounds, valued at $191,933, but this does not include the quantity of potash produced and consumed in the same establishments in the manufacture of soft soap. These are two of the industries in which the largest quantities of potashes are used.

Table 41 shows the imports and exports of potashes and ashes as taken from Commerce and Navigation of the United States, published by the Bureau of Statistics.

[1] Fused.

[2] Includes some refined admitted free.

CLASS IV.—ALUMS.

The class of alums comprises potash, ammonia and soda alums, and all other double sulphates of aluminum with the alkali metals, or their isomorphs, such as chrome alum; burnt alum, known also as dried alum and alumen exsiccatum, or ustum; porous alum, which is effloresced soda alum, or else the product obtained by mixing soda ash with alum cake; aluminum sulphate; concentrated alum, which is crystallized aluminum sulphate; alum cake, which is crude aluminum sulphate; alumino-ferric cake, which is alum cake containing a considerable amount of iron; and aluminum hydrate, or hydroxide.

Statistics for the alum industry have been reported separately at each census beginning with that of 1880. At the census of 1900 the quantity and value of each of the chief varieties of alums were also set forth.

TABLE 42.—*Alums—comparative summary, with amount and per cent of increase: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Number of establishments	8	4	4	100.0
Capital	$11,836,933	$5,553,313	$6,283,620	113.2
Salaried officials, clerks, etc., number	87	27	60	222.2
Salaries	$135,226	$64,328	$70,898	110.2
Wage-earners, average number	2,559	1,496	1,063	71.1
Total wages	$1,331,776	$773,356	$558,420	72.2
Miscellaneous expenses	$467,113	$214,997	$252,116	117.3
Cost of materials used	$2,583,173	$1,318,906	$1,264,267	95.9
Value of products[1]	$5,058,395	$2,882,421	$2,175,974	75.5

[1] Includes "all other products."

Table 42 presents the statistics for the principal establishments only. An increase is shown in every item, the largest per cent of increase being in the number of salaried officials, clerks, etc., and the next largest being in miscellaneous expenses.

TABLE 43.—ALUMS—QUANTITY AND VALUE: 1880 TO 1905.

CENSUS.	Establishments.	Quantity (pounds).	Value.	INCREASE.			PER CENT OF INCREASE.		
				Establishments.	Quantity (pounds).	Value.	Establishments.	Quantity (pounds).	Value.
1905	17	225,543,308	$2,956,844	4	40,898,011	$440,424	30.8	22.1	17.5
1900	13	[1] 184,645,297	[1] 2,516,420	3	90,647,289	899,710	30.0	96.4	55.7
1890	10	93,998,008	1,616,710	4	54,780,283	808,545	66.7	139.7	100.0
1880	6	39,217,725	808,165	.....	.....	.....	.....	.....	.....

[1] Includes 5,177,826 pounds, with an assigned value of $69,844, consumed in establishments where manufactured; and also the alum reported by establishments engaged primarily in the manufacture of other products.

The data of Table 43 shows, when the industry is considered as a whole as well as when only the operation of the principal establishments is considered, that there has been an increase in every item at each succeeding census, and that the industry was in a flourishing condition at the census of 1905. A comparison of the increases at the various periods shows that while the greatest percentage of increase in every item occurred in the interval from 1880 to 1890, the largest actual increase in both quantity and value occurred in the interval from 1890 to 1900. It is to be observed that the data for 1900 includes the quantity and value of alum which was produced and consumed. No information on this point is available for 1905.

TABLE 44.—*Kinds of alum—quantity and value of products: 1905 and 1900.*

KIND.	1905		1900	
	Pounds.	Value.	Pounds.	Value.
Total	225,543,308	$2,956,844	179,467,471	$2,446,576
Ammonia alum	3,467,104	59,774	6,580,373	102,308
Burnt alum	15,858,335	364,328	6,628,914	174,600
Concentrated alum	80,919,272	972,892	103,016,815	1,062,547
Potash alum	10,307,154	156,448	14,200,393	215,004
Soda alum	82,050	4,923	9,399,550	228,500
Alum cake	19,496,047	161,906	4,048,655	34,047
Other alums	95,413,346	1,236,573	35,592,771	629,570

The data of Table 44 shows that a larger proportion of the alums returned at the census of 1905 is included under the heading "other alums" than at the census of 1900, and that there has been a decrease in every other item, except in the quantity and value of burnt alum and of alum cake, items which show marked increases. The greatest decrease is in the quantity and value of soda alum, but, as pointed out in the special report for 1900, this is often included under burnt alum; there is reason for this, since as sold it does not usually contain the water of crystallization, which is characteristic of the crystallized alums. Some manufacturers contend that soda alum, which is known in trade as "C. T. S.," or "cream of tartar substitute," is not an alum, and accordingly they may have reported it under "all other products." This would reduce the total quantity and value of alums and may be an additional means of explaining why the increases shown for the industry at the census of 1905 are not proportionate to those shown at the census of 1900.

TABLE 45.—*Alums—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	[1] 17	[1] 13
California	1	.....
Illinois	3	1
Massachusetts	3	3
Michigan	1	1
New York	2	2
Ohio	1	.....
Pennsylvania	6	6

[1] Includes 9 establishments engaged primarily in the manufacture of other products.

Table 45 shows the same number of establishments in operation at the censuses of 1905 and 1900 in every state except Illinois, where there has been a gain of 2 establishments, and California and Ohio, in each of which 1 plant has been established. Pennsylvania stands first at each census. Massachusetts stands second at each, being joined in this place at the census of 1905 by Illinois. No other state had more than 2 establishments at either census.

TABLE 46.—*Alums—value of products, by states: 1905 and 1900.*

STATE.	1905	1900
United States	$2,956,844	$2,446,576
Pennsylvania	1,479,340	1,411,652
Massachusetts	270,614	306,754
Illinois	481,754	(1)
All other states [2]	725,136	728,170

[1] Included in "all other states."
[2] Includes in 1905 California, Michigan, New York, and Ohio; in 1900, Illinois, New York, and Michigan.

Table 46 shows that at each census Pennsylvania stood first in the value of alums produced and "all other states" second. It also shows for the later census a decrease in the value of the product for Massachusetts, and an apparent decrease for "all other states," but as the value of the product from Illinois was reported separately at the census of 1905, while it was included in the item "all other states" for 1900, the only real decrease is in the returns for Massachusetts.

In the census year 1900 there were used in the manufacture of alums, including those produced and consumed, 39,000 tons of bauxite, valued at $263,850; 5,000 tons of cryolite, valued at $110,000; 2,000 tons of sodium sulphate, in the form of salt cake or niter cake, valued at $4,100; 755 tons of soda ash, valued at $8,744; 360 tons of ammonium sulphate, valued at $21,900; 477 tons of potassium sulphate, valued at $19,600; and 71,426 tons[1] of sulphuric acid, in the manufacture of which were used 3,323 tons of sulphur (valued at $66,000), 28,358 tons of pyrites (valued at $133,282), and 720 tons of sodium nitrate (valued at $25,200). In 1905 there were used in this industry 53,246 tons of bauxite, valued at $423,643; 4,867 tons of aluminum hydrate, or hydroxide, valued at $223,882; 4,141 tons of sodium sulphate, valued at $11,627; 8,657 tons of soda ash, valued at $162,394; 179 tons of ammonium sulphate, valued at $11,165; 1,288 tons of potassium sulphate, valued at $55,951; and 80,672 tons of sulphuric acid of 50° Baumé, in the manufacture of which were used 38,233 tons of pyrites (valued at $187,341) and 807 tons of sodium nitrate (valued at $32,280).

Table 47 shows the imports of alums and materials for alum making as taken from Commerce and Navigation of the United States, published by the Bureau of Statistics.

[1] Recalculated from ascertained yields in practice.

CLASS V.—COAL TAR PRODUCTS.

The class of coal tar products comprises the materials obtained by the distillation of coal tar, known as coal tar distillery products, which include pitch, creosote oil, dead oil and other tar oils, benzol (benzene), toluol, xylol, naphthalene, anthracene and other coal tar hydrocarbons, phenol (carbolic acid), cresol, naphthol, resorcin, or resorcinol, and other coal tar tertiary alcohols, and aniline, toluidine, xylidine, and other coal tar amines; and chemicals made from coal tar distillery products, which include the aldehydes, acids, ketones, salts, and various other so-called benzene derivates. These cover the so-called coal tar dyes, which appear also under "dyestuffs," and many nitro-substitution compounds and synthetic preparations, which appear again under "essential oils" or "fine chemicals." There is a further duplication in that many establishments in which coal tar is distilled consume part of the product in the further manufacture of roofing felt, roofing paper, and roofing preparations which belong either in the class of "roofing and roofing materials" or of "paints." These duplications are necessary in order to show the condition of the industry as a whole. In view of these facts it is evident that the classifying of the coal tar products presents very serious difficulties and that for this industry there will necessarily be at the different censuses variations in the statistics.

TABLE 48.—*Coal tar products—comparative summary, with amount and per cent of decrease: 1905 and 1900.*

	CENSUS.		Decrease.	Per cent of decrease.
	1905	1900		
Number of establishments	6	15	9	60.0
Capital	$837,991	$2,095,363	$1,257,372	60.0
Salaried officials, clerks, etc., number	41	84	43	51.2
Salaries	$65,802	$152,817	$87,015	57.0
Wage-earners, average number	129	514	385	74.9
Total wages	$70,972	$257,838	$186,866	72.5
Miscellaneous expenses	$114,389	$190,041	$75,652	39.8
Cost of materials used	$538,617	$1,341,561	$802,944	59.9
Value of products	$820,309	$2,227,544	$1,407,235	63.2

Table 48 shows a decrease in every item for 1905 as compared with 1900, the greatest percentage of decrease being in the average number of wage-earners and in wages paid, and the least in miscellaneous expenses. The cause of the decreases is due chiefly, if not entirely, to the fact that establishments which in 1900 produced coal tar distillery products as their principal product and roofing materials as a subsidiary product, in 1905 produced roofing materials as their principal product, and were thus taken out of the class of coal tar products establishments. It is pointed out, in the special report on this industry for the census of 1900, that tarred felt and tarred paper, in which part of the material produced from the coal tar was consumed in further manufacture, were produced to the value of $442,529.

Statistics for this industry were first reported separately at the census of 1880, since which time they have been reported separately at each census. As no data are at command by which to ascertain the quantity of the coal tar products which were produced and consumed, these statistics show only the totals of those products produced for sale.

TABLE 49.—*Coal tar products—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	[1] 39	[2] 22
California	1	1
Illinois	1	.....
Louisiana	.....	1

Rhode Island	1	.....
Tennessee	1	1

[1] Includes 33 establishments engaged primarily in the manufacture of other products.
[2] Includes 7 establishments engaged primarily in the manufacture of other products.

Table 49 shows that there has been an increase of 17 in number, or 77.3 per cent, for the establishments

in the United States for 1905 as compared with 1900, the increases for the individual states reporting in 1900 being 6 in New Jersey, 5 in New York, and 1 in Ohio, while Maine reports 3 establishments and Illinois, Michigan, and Rhode Island 1 each for the first time at the census of 1905. Louisiana and Minnesota which reported 1 establishment each in 1900 did not report any in 1905. At the census of 1900 Pennsylvania stood first in the number of establishments, with Missouri and New York sharing second place. No other state returned more than 2 establishments. At the census of 1905 New Jersey and New York shared first place, Pennsylvania occupied second, and Maine, Massachusetts, Missouri, and Ohio shared third. No other state returned more than 1 establishment.

[1] Showing value of coal tar products only.
[2] Included in "all other states."
[3] Includes in 1905 California, Illinois, Michigan, Rhode Island, and Tennessee; in 1900, California, Louisiana, Massachusetts, Minnesota, New Jersey, Ohio, and Tennessee; in 1890, Massachusetts and Tennessee.

The rank of the states at the different censuses, as determined by the value of products, has varied in an erratic manner. New Jersey, which ranked first in 1890 and again in 1905, was classified under "all other states" in 1900; Missouri, which ranked first in 1900, took the fifth place in 1905; and Pennsylvania, which ranked second in 1900, passed to the fourth place in 1905; New York, which ranked third in 1890 and in 1900, rose to the second place in 1905; Ohio, which had not been reported separately at any previous census, took the third place in 1905. At each census the largest portion of the product has been reported from the Middle Atlantic states.

Coal tar is produced in the destructive distillation of bituminous coal, and is therefore a by-product of the coal gas industry and, when by-product ovens are used, of the coke industry. The unit of measure used in treatises on this material is sometimes gallons and sometimes tons. But since a gallon of coal tar weighs, on an average, 10 pounds, it is a simple matter to convert the quantities given in one of these units into terms of the other. At the census of 1900[1] it was estimated that the quantity of coal tar produced in the gas industry in this country was 67,094 tons, and the quantity of water gas tar produced, 222,868 tons. At the census of 1905[2] the quantity of tar reported was 67,515,421 gallons, or 337,577 tons. This includes both the coal tar from the straight coal gas process, and the water gas tar produced chiefly in carbureting the water gas. As the two processes are often carried on in conjunction, it is not a simple matter for the producers to give separate returns for them, and hence a combined return was received. Assuming, however, that the ratio of each approximated that reported for the census of 1900, which was closely 23 of coal gas tar to 77 of water gas tar, the amount reported for the census of 1905, in the gas industry, was equivalent to 77,643 tons of coal tar and 259,934 tons of water gas tar. In the coke industry, at the same census, the quantity of coal tar reported was 26,223,323 gallons, or 131,117 tons.[3] There was therefore available in the United States in 1905, 208,760 tons of coal tar as compared with 119,438 tons in 1900, and 468,694 tons of coal and water gas tar as compared with 342,306 tons in 1900. It is to be noted that at the later census the coal tar production from coke ovens exceeded that from coal gas plants. The amount of coal tar reported as used in the United States at the census of 1900 was 110,023 tons, and at the census of 1905, 127,756 tons; at the later census there were also reported as used 117,459 tons of oil gas tar.

Among the products of this industry reported at the census of 1905 were 61,100 tons of pitch, valued at $800,862; 577,750 gallons of refined coal tar, valued at $22,704; 18,750 gallons of ready mixed paints, valued at $5,621, these three products evidently having been made from coal tar pitch and light distillate; 288,817 gallons of creosote oil, valued at $17,546; 17,175 tons of oils, including light, heavy, and dead oils, and probably some creosote oil, valued at $308,830; coal tar distillery products, probably comprising some of the foregoing, valued at $7,613; 5,872,360 pounds of coal tar dyes, valued at $2,348,189; and 2,391,866 pounds of chemicals made from coal tar distillery products, including salicylic acid and its derivatives, saccharine, and phenol preparations and derivatives, valued at $569,024. It is believed that many of these are lost in the classifications "druggists' preparations" and "patent medicines and compounds." At the census of 1900 the chemicals made from coal tar distillery products were valued at $205,047. Pyridine and its homologues, some of these chemicals, are used for denaturing alcohol, and, as the Commissioner of Internal Revenue has ruled that alcohol denatured by their use may be used tax free in the arts and manufactures and for domestic purposes, it is reasonable to suppose that in subsequent census returns these substances may be enumerated as separate items.

[1] Twelfth Census, Manufactures, Part IV, page 549.

[2] Census of Manufactures, 1905, Bulletin 57, page 42.

[3] Census of Manufactures, 1905, Bulletin 65, page 17.

A comparison of the coal tar reported as used in the manufacture of coal tar products, with the coal tar produced in the coal gas and coke industries, shows that in 1900 there was used in the manufacture of coal tar products 92.1 per cent of the entire amount produced, and in 1905 but 61.2 per cent; at the latter census the amount of oil gas tar used nearly equaled that of the coal tar. These figures indicate that other and increasing uses for coal tar than that of converting it into coal tar products are being found, such for instance as employing it for fuel in internal combustion engines of the Diesel type. Despite these uses, however, our resources for tar are by no means exhausted; it is estimated that in 1905, 28 per cent of the tar produced in by-product coke works was consumed as fuel in the works, and it is shown in the bulletin on coke for 1905,[1] that had all the coal which was coked in that census year been coked in by-product ovens, at the average rate of yield which obtained for the coal actually so coked, there would have been produced 295,273,173 gallons, or 1,476,366 tons, of coal tar from that source alone. There is therefore no lack of coal tar for our industries. In fact, the difficulty of profitably disposing of that now produced is a large factor in delaying the erection of additional by-product coke plants. Nor is there yet any restriction on the amount of benzene and its homologues available for use in the aniline dye industry, for, besides that which occurs in the coal tar, a considerable amount, which might be utilized, is allowed to pass off in the gas from by-product ovens. Of the 10,000 cubic feet of gas produced from a ton of coal, 6,500 cubic feet are required in the coking process. This gas contains three-fourths of 1 per cent of benzene and its homologues, which may be removed by washing the gas with petroleum, or coal tar oil; the product thus obtained is a benzolized oil containing from 2 to 3 per cent of benzene. On distillation a crude benzene light oil is obtained which contains only slight quantities of impurities, such as carbon disulphide, hydrogen sulphide, thiophene, and naphthalene, which by purification and redistillation yields a 100 per cent pure benzene,[2] suitable for converting into aniline. The extraction of the benzene and its homologues does not seriously affect the heating value of the gas, and is now being practiced to some extent. At the census of 1905 the volume of gas reported as produced and consumed in by-product ovens was 16,232,309 thousand cubic feet. The volume which would have been produced had all of the coal which was coked in that year been coked in by-product ovens is estimated at 183,025,147 thousand cubic feet.

The statistics given in Tables 48 and 50 show that the manufacture of coal tar products in the United States is an important and a growing industry, yet when compared with the same industry in Germany it sinks into insignificance.

1904	38,277	83,323	391,645	522,242
1905	46,057	114,500	468,352	645,830

[1] These preparations are known as benzol, toluol, naphthalin, xylol, phenol, cresol, toluidine, xylidin, cumidin, binitrotoluol, binitrobenzol, benzidin, tolidin, dianisidin, naphthol, naphthylamin, diphenylamin, benzaldehyde, benzyl chloride, resorcin, nitrobenzol, and nitrotoluol.
[2] Not reported separately.

CLASS VI.—CYANIDES.

The class of cyanides comprises potassium cyanide (cyanide of potash, or white prussiate of potash), sodium cyanide, and other simple cyanides including "cyan-salt," which is a mixture of potassium and sodium cyanides; potassium ferrocyanide (yellow prussiate of potash) and potassium ferricyanide (red prussiate of potash); the cyanates, ammonium and potassium sulphocyanates (thiocyanates or sulphocyanides), and other sulphocyanates; and cyanamids.

TABLE 52.—*Cyanides—comparative summary, with amount and per cent of decrease: 1905 and 1900.*

	CENSUS.		Decrease.	Per cent of decrease.
	1905	1900		
Number of establishments	6	12	6	50.0
Capital	$342,233	$1,250,941	$908,708	72.6
Salaried officials, clerks, etc., number	7	20	13	65.0
Salaries	$12,538	$36,475	$23,937	65.6
Wage-earners, average number	113	376	263	69.9
Total wages	$72,768	$190,568	$117,800	61.8
Miscellaneous expenses	$71,332	$173,133	$101,801	58.8
Cost of materials used	$348,490	$1,283,949	$935,459	72.9
Value of products	$586,581	$1,769,736	$1,183,155	66.9

The statistics of Table 52 show a decrease in every item, the greatest in amount being in value of products and the greatest percentage in cost of the materials used and in capital. This comparison is made between those establishments only in which the cyanides are the principal products. Since in 1900, several establishments produced a notable amount of subsidiary products, part of this reduction may be accounted for through these subsidiary industries outgrowing the cyanide industry in such establishments, and thereby carrying these establishments into another Census classification.

A better idea of the condition of the industry at the census of 1905 may be gained by bringing together the quantity and value of the cyanides produced either as a principal or as a subsidiary product, and comparing these results with similar ones for the census of 1900, the first census at which the cyanides were reported separately.

TABLE 53.—*Cyanides—quantity and value of products, with amount and per cent of increase: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Quantity, pounds	11,196,318	8,460,989	2,735,329	32.3
Value	$1,710,823	$1,595,505	115,318	7.2
Value per pound	$0.153	$0.189	.....	.....

The statistics of Table 53 show an increase in each item reported, though the increase in value is relatively less than the increase in quantity. The cyanide process for the extraction of precious metals from their ores was first made commercially successful in 1890. Its introduction into this country was slow at first, but very rapid after its utility was once demonstrated. In 1905 there were 132 establishments operating in the United States in which the cyanide process was used. When the rapid increase in the use of cyanides for this purpose and the constant increase in their use in the textile and paint industries are considered, and especially when, as shown in Table 56, it is found that the imports for consumption of cyanide of potash and of yellow prussiate of potash were less in 1905 than in 1900, while the imports of red prussiate of potash were but slightly greater, it is believed that the statistics available at the census of 1905 do not fairly represent the condition of the cyanide industry. There are probably two reasons to account for this: The first, that possibly some manufacturers, instead of making separate returns for the cyanides which they produced for sale or used in further manufacture, have reported them under "all other products;" and the second, that possibly some of the larger consumers, such as those engaged in the manufacture of printed fabrics, or paints, or inks, have begun the manufacture of the cyanides consumed by themselves in further manufacture, and, in cases where this manufacture is, relatively to the principal product of the establishment, of very minor importance, it has been found difficult to secure separate returns.

TABLE 54.—*Cyanides—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900
United States	[1] 11	[2] 18
Maryland	.....	1
Massachusetts	1	1
Michigan	1	.....
Missouri	1	3
New Jersey	1	6
New York	2	.....
Ohio	2	3
Pennsylvania	3	4

[1] Includes 5 establishments engaged primarily in the manufacture of other products.
[2] Includes 6 establishments engaged primarily in the manufacture of other products.

Table 54 shows a decrease of 7, or 38.9 per cent, in the number of establishments of all classes manufacturing cyanides at the census of 1905 as compared with that of 1900. The largest decrease is in New Jersey, which returned 6 establishments in 1900 and but 1 in 1905. The other decreases are 2 in Missouri, and 1 each in Maryland, Ohio, and Pennsylvania. At the census of 1900 New Jersey ranked first and Pennsylvania second. At the census of 1905 Pennsylvania ranked first, with 3 establishments, while New York and Ohio each had 2 establishments.

TABLE 55.—*Cyanides—value of products,[1] by states: 1905 and 1900.*

STATE.	1905	1900
United States	$1,710,823	$1,595,505
New Jersey	.....	1,053,472
Pennsylvania	434,770	303,245
Ohio	.....	86,852
All other states[2]	1,276,053	151,936

[1] Includes value of cyanides only.
[2] Includes in 1905 Massachusetts, Michigan, Missouri, New Jersey, New York, and Ohio; in 1900, Louisiana, Tennessee, Ohio, California, Minnesota, Massachusetts, and New Jersey.

The statistics of Table 55 show that New Jersey, which is included in "all other states" in 1905, returned 66 per cent of the total value of products in 1900. In both Pennsylvania and "all other states" there is an increase at the later census. The increase in "all other states" is due partly to the fact that the statistics for New Jersey and Ohio, which in 1900 were set forth separately, can not be shown in 1905, because less than 3 establishments reported. It is worthy of note, considering the extent to which the cyanides are used in metallurgical processes in the far West, that their manufacture is largely confined to the Eastern states.

At the census of 1900 there were reported[1] as used in this industry, 9,315,080 pounds of potassium carbonate, valued at $279,602; 3,456 tons of hoofs and of horn waste, valued at $87,502; 19,417 tons of scrap leather, valued at $150,213; 1,200 tons of spent iron oxide from gas works, valued at $3,000; 300,000 pounds of sodium, valued at $93,183; 2,400 bushels of lime, valued at $480; scrap iron, valued at $9,520; and 2,401,180 pounds of potassium ferrocyanide.

At the census of 1905 there were reported as used 9,981,700 pounds of potassium carbonate, valued at $215,664; 1,279,447 pounds of sodium carbonate, valued at $5,037; 13,478 tons of scrap leather, valued at $87,253; 3,248 tons of spent iron oxide, valued at $25,146; 2,478,966 pounds of sodium; 40,034 bushels of lime, valued at $6,112; 175 tons of scrap iron, valued at $7,000; and 54,966 pounds of potassium ferrocyanide, valued at $7,695.

Among the cyanides reported at the census of 1900[1] there were 6,165,407 pounds of potassium ferrocyanide, valued at $994,014, and 2,317,280 pounds of so-called potassium cyanide, valued at $601,491. At the census of 1905 there were reported produced, 5,027,264

[1] Twelfth Census, Manufactures, Part IV, page 553.

pounds of potassium ferrocyanide, valued at $683,277; 78,584 pounds of potassium cyanide, valued at $17,438; and 6,197,470 pounds of sodium cyanide, valued at $923,210.

At a meeting of the Fifth International Congress of Applied Chemistry held in Berlin in 1903, Mr. George Beilby said that the whole "turnover" of the European trade at its best, in the cyanide industry, did not exceed $2,919,000 a year, and that the total net profit in the best year was probably under, rather than over, $486,650. He estimated that the consumption of European-made cyanide throughout the world, not counting that exported to America, was normally about 5,500 tons per annum, while the capacity of the then existing works in Germany, France, and Great Britain was 12,600 tons, and with the then proposed additions would soon be 15,700 tons per annum. He said also that on account of the congestion of the European market during the two or three previous years, relief had been sought through exports to America at a low price. He referred to the new industrial sources of the cyanides, such as the "Schlempe," or residue of the beet root molasses refineries, which through Bueb's process had been made to yield a gas very much richer in ammonia and hydrocyanic acid than coal gas; to the improved processes for the production of the cyanides and ferrocyanides from coal gas; to the improved Gelée process for the production of ammonium sulphocyanide from carbon disulphide and ammonia, and its further conversion into ferrocyanide; and to the Siepermann and his own process for obtaining cyanide from potassium carbonate, charcoal, and ammonia. At the same Congress, Dr. F. Rössler traced the development of the synthetic processes of manufacture. Descriptions of all these processes are given in great detail in the recently published book of Robine and Lenglen.

The most important discovery in the cyanide industry, in the interval which has elapsed since the last census, is in the manufacture of calcium cyanamid, or lime nitrogen, by the process of Frank and Caro, which consists practically of the passage of nitrogen over heated calcium carbide, for in this is found a practical and economical process for the fixation of atmospheric nitrogen, a further use for calcium carbide, and a valuable and very extensive field for the utilization of liquid air; while the product itself is a valuable fertilizer, which may be used directly as such. Furthermore, by very simple means a considerable number of useful chemicals may be produced from it, among which may be mentioned potassium and other cyanides, ammonia and ammonium sulphate or other ammoniacal salts, urea, guanidin, dicyandiamid, and nitric acid. Since this process was discovered, between 8,000 and 9,000 gross tons of lime nitrogen have been manufactured by it, and for more than a year past a plant having a capacity of 3,750 gross tons per year has been in operation at Piano d'Orta, Italy. This plant is engaged in enlarging its capacity to 15,000 gross tons per year, while other plants having a combined capacity of 26,250 gross tons per year are under construction in Europe. There is little doubt but that this industry will have been established in this country by the time of the taking of the next census, and that its stimulating effect on related industries will be noted.

Table 56 shows the imports of cyanides from 1891 to 1905, as taken from Commerce and Navigation of the United States, published by the Bureau of Statistics.

CLASS VII.—WOOD DISTILLATION.

The class of wood distillation comprises wood alcohol (methyl alcohol), both crude and refined, acetate of lime (calcium acetate), both brown and gray, acetate of soda, acetic acid, charcoal, formaldehyde, acetone, pyroligneous acid, pyrolignite of iron, dye liquors, wood creosote, wood oil, wood tar, wood ashes, spirits of turpentine, as produced by the distillation of wood, pine oil, red liquor, wood preservative, tar

oil, and pine tar. Naturally spirits of turpentine and rosin, with other products, obtained from the distillation of the exuded turpentine of the long leaf pine are reported under the classification of "turpentine and rosin."

TABLE 57.—*Wood distillation—comparative summary, with amount and per cent of increase: 1905 and 1900.*

	CENSUS.		Increase.	Per cent of increase.
	1905	1900		
Number of establishments	141	102	39	38.2
Capital	$10,506,979	$6,729,127	$3,777,852	56.1
Salaried officials, clerks, etc., number	301	235	66	28.1
Salaries	$297,528	$213,025	$84,503	39.7
Wage-earners, average number	2,272	1,556	716	46.0
Total wages	$1,066,786	$700,484	$366,302	52.3
Miscellaneous expenses	$631,437	$368,305	$263,132	71.4
Cost of materials used	$4,847,770	$3,455,015	$1,392,755	40.3
Value of products	$7,813,483	$6,001,023	$1,812,460	30.2

Table 57 shows a marked increase in every item, the largest percentage of increase being in the item of miscellaneous expenses. A more significant increase is in the item of capital, which shows nearly double the percentage of increase that the value of products does. A part of this increase is due to the introduction into the South and West of distillation processes for the treatment of pine wood and stumpage.

Statistics for this industry were reported separately at the census of 1880 and have been reported separately at each subsequent census. The figures given in 1880 were for crude wood alcohol, acetate of lime, and charcoal, and for purposes of comparison the figures for these items are shown in Tables 58 and 59 for each census. Since 1880, following the general trend of the development of chemical manufactures, a number of establishments manufacturing these crude products have used the crude alcohol for the production of refined alcohol, which is the form in which this product is offered for sale. In the process of refining, the crude alcohol is reduced in volume by about 20 per cent. To ascertain the total volume of crude alcohol produced by wood distillation processes at any given census, it is necessary, not only to add together all of the crude alcohol produced as a subsidiary product, but also to include that which is consumed in the wood distillation establishments in further manufacture. Frequently this is not reported, but, knowing the volume of refined alcohol produced, the volume of the crude alcohol can be determined with a close approach to accuracy by multiplying the quantity of refined alcohol by 1.25. Such a method of procedure was followed at the census of 1890, and has been followed at each subsequent census.

TABLE 58.—WOOD DISTILLATION—CRUDE PRODUCTS: 1880 TO 1905.

CENSUS.	Number of establishments.	WOOD ALCOHOL (CRUDE).		ACETATE OF LIME.		CHARCOAL.	
		Gallons.	Value.	Pounds.	Value.	Bushels.	Value.
1905	129	[1] 8,282,286	[1] $2,672,507	110,383,997	$1,527,733	[2] 40,944,190	[2] $2,038,514
1900	93	4,945,963	1,976,986	86,826,000	981,286	17,154,302	726,672
1890	53	1,116,075	688,764	26,778,415	315,430	.....	.....
1880	17	.....	86,274	6,593,009	156,892	.....	31,770

[1] Includes 1,468,028 gallons, with an assigned value of $470,546, consumed in establishments where manufactured.
[2] Includes 11,026,978 bushels of charcoal, with an assigned value of $551,349, consumed in establishments where manufactured.

TABLE 59.—WOOD DISTILLATION—CRUDE PRODUCTS, INCREASE AND PER CENT OF INCREASE: 1880 TO 1905.

KIND.	INCREASE.						PER CENT OF INCREASE.					
	1900 to 1905		1890 to 1900		1880 to 1890		1900 to 1905		1890 to 1900		1880 to 1890	
	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.
Wood alcohol (crude), gallons	3,336,323	$695,521	3,829,888	$1,288,222	.....	$602,490	67.5	35.2	343.2	187.0	.....	698.3
Acetate of lime, pounds	23,557,997	546,447	60,047,585	665,856	20,185,406	158,538	27.1	55.7	224.2	211.1	306.2	101.0
Charcoal, bushels	23,789,888	1,311,842	.....	.....	.....	.....	138.7	180.5	.....	.....	.....	.....

Table 59 shows an increase in every item at each census, indicating a constant progress in every branch of the industry.

Table 60 shows that the number of establishments has increased by 39, or 35.1 per cent, in 1905 as compared with 1900, the greatest increase in any one state being in Georgia, which reported 9 in 1905 as compared with none in 1900. The increase in Michigan was 7, in South Carolina 5, and in New York, North Carolina, and Pennsylvania 4 each. It will be observed that a large part of the gain is to be credited to the Southern states.

TABLE 60.—*Wood distillation—number of establishments, by states: 1905 and 1900.*

STATE.	1905	1900

Vermont	2	1
Washington	1	.....
Wisconsin	1	.....

[1] Includes 9 establishments engaged primarily in the manufacture of other products.

Ranked by the number of establishments, Pennsylvania stood first at each census, New York second, and Michigan third. Georgia in 1905 stands fourth, North Carolina fifth, South Carolina sixth, and Florida seventh. No other state reported more than 2 establishments.

TABLE 61.—*Wood distillation—value of crude products,[1] by states: 1905 and 1900.*

STATE.	1905	1900
United States	$6,538,769	$3,833,266
Georgia	78,313	.....
Michigan	1,343,163	505,069
New York	1,222,383	786,252
North Carolina	74,501	18,409
Pennsylvania	3,127,350	2,339,536
South Carolina	15,419	.....
All other states	677,640	184,000

[1] Includes crude products manufactured by establishments engaged primarily in the manufacture of other products.

At the census of 1900 Pennsylvania ranked first in the value of its crude products, New York second, and Michigan third. At the present census Pennsylvania ranks first, Michigan second, and New York third. At the census of 1900 the value of the crude products of Pennsylvania, New York, and Michigan amounted to $3,630,857, and constituted 94.7 per cent of the total for the United States, while at the census of 1905 it amounted to $5,692,896, and constituted 87.1 per cent of the total.

At the census of 1900 there were 9 establishments reporting the production of the crude material and the refining of the alcohol in the same factory. These establishments produced 637,856 gallons of refined alcohol, valued at $370,513; 5,124,000 pounds of acetate of lime, valued at $54,928; and 2,726,120 bushels of charcoal, valued at $114,663. At the census of 1905 the number of establishments thus reporting was 8, which produced 1,210,736 gallons of refined alcohol, valued at $503,884; 10,718,089 pounds of acetate of lime, valued at $110,517; and 9,275,543 bushels of charcoal (including 3,035,100 bushels produced and consumed) valued at $536,926.

The quantity of wood used in this industry at the census of 1900 was 490,939 cords, valued at $1,241,972, or an average of $2.53 per cord. Of this, 3,134 cords, valued at $7,822, consisted of soft wood, namely, long leaf pine. The quantity of wood used at the census of 1905 was 1,049,503 cords, valued at $3,755,627, or an average of $3.58 per cord. Of this, 31,431 cords, valued at $112,742, consisted of soft wood, principally long leaf pine. It was estimated in 1900, on the assumption that one man could cut on the average 1½ cords of wood per day, that the cutting of the wood required for the wood distillation industry for that year gave employment to 3,273 men for one hundred days each. The cutting of the wood required for the census year 1905 at the same rate would have given employment to 6,997 men for one hundred days each.

Up to the census of 1900 the wood distillation industry was confined to the distillation of the hardwoods, but at the census of 1900, 4 establishments were reported as being engaged in the distillation of pine wood, and at the census of 1905, 31 establishments were reported as being so engaged. The products of the distillation of pine wood are so unlike those of hardwoods that the statistics of the two industries should be reported separately. This was not done in the report on chemicals and allied products at the census of 1900, because the quantity and value of such products were relatively insignificant, but the growth of the industry requires that this now be done.

TABLE 62.—*Pine wood distillation products: 1905 and 1900.*

KIND.	1905		1900	
	Quantity.	Value.	Quantity.	Value.
Total	.....	$376,874	.....	$31,148
Wood alcohol, gallons	18,000	1,800	62,238	7,570
Pyroligneous acid, gallons	277,500	8,005	12,296	316
Turpentine spirits, gallons	409,685	176,521	.....	.....
Tar, gallons	1,292,983	75,923	.....	.....
Tar oil, gallons	176,849	8,076	170,960	13,677
Charcoal, bushels	342,320	25,046	1,138	137
All other kinds	.....	81,506	.....	9,448

Table 62 shows an increase of $345,726, or of 1,109.9 per cent in the total value of products for 1905 as compared with 1900, and an increase also in every separate item for which a comparison is made except in the quantity and value of the wood alcohol and in the value of tar oil. Furthermore, an increased number of products is shown for 1905 as compared with 1900, which indicates a marked improvement in manufacturing methods and a more complete utilization of the distillation product.

Table 63 shows that the increase in the quantity of refined wood alcohol at the census of 1900 over that of 1890 was 2,871,798 gallons, or 1,726.4 per cent, and that

the increase at the census of 1905, as compared with that of 1900, was 2,879,013 gallons, or 94.8 per cent, in quantity, and $1,158,727, or 50.4 per cent, in value.

The quantity of lime used at the census of 1900 was 524,508 bushels, valued at $86,635, or an average of $0.165 per bushel, and at the census of 1905, 811,902 bushels, valued at $120,181, or an average of $0.148 per bushel.

TABLE 63.—*Production of refined wood alcohol: 1890 to 1905.*

CENSUS.	Number of establishments.	Gallons.	Value.
1905	15	5,917,153	$3,455,625
1900	18	3,038,140	2,296,898
1890	4	166,342	.....

The quantity of caustic soda returned as used at the census of 1900 was 1,270,846 pounds, valued at $33,717, and at the census of 1905, 346,150 pounds, valued at $4,158. This very considerable shrinkage is believed to be due to the failure of refiners to make separate returns for this item of materials used. Chloride of lime, sulphuric acid, and muriatic acid were also reported at each census among the materials used, but the quantities were not sufficiently large to warrant them being presented separately.
